Carbon Cryogel Silicon Composite Anode Materials for Lithium Ion Batteries

A variety of materials are under investigation for use as anode materials in lithium-ion batteries, of which, the most promising are those containing silicon.\(^{10}\) One such material is a composite formed via the dispersion of silicon in a resorcinol-formaldehyde (RF) gel followed by pyrolysis. Two silicon-carbon composite materials, carbon microspheres and nanofoams produced from nano-phase silicon impregnated RF gel precursors have been synthesized and investigated. Carbon microspheres are produced by forming the silicon-containing RF gel into microspheres whereas carbon nano-foams are produced by impregnating carbon fiber paper with the silicon containing RF gel to create a free standing electrode.\(^1\,4\,9\) Both materials have demonstrated their ability to function as anodes and utilize the silicon present in the material. Stable reversible capacities above 400 mAh/g for the bulk material and above 1000 mAh/g of Si have been observed.
Carbon Cryogel Silicon Composite Anode Materials for Lithium-Ion Batteries

**Lithium Ion Basics**

**Cathode**
- Transition Metal Oxide
- LiCO₂

Capacity is dependent on number of Li⁺ ions that can be shuttled back and forth.

**Anode**
- Most Commonly Carbon
- Graphite
- Hard Carbon

**Charge**

**Cathode**
- LiMO₂ → Li_{1-x}MO₂ + xLi⁺ + xe⁻

**Discharge**
- Li_{1-x}MO₂ + xLi⁺ + xe⁻ → LiMO₂

**Anode**
- C + xLi⁺ + xe⁻ → LiₓC

**Discharge**
- LiₓC → C + xLi⁺ + xe⁻
NASA Goals

• Future missions of the National Aeronautics and Space Administration (NASA) require advanced energy storage systems
  – High specific energies (Wh/kg)
  – High energy densities (Wh/l)
• Develop advanced lithium ion cells
• Anode development is a key component
• the anode represents 24% of cell mass and additional opportunity for cell mass reduction
• Key performance parameters
  – Threshold value of 600 mAh/g
  – Goal of 1000 mAh/g

Estimates for component weight fraction in 30 Ah cell
Anode Materials

- **Graphite**
  - Excellent cycling characteristics
  - Theoretical capacity of 372 mAh/g \((\text{LiC}_6)\)

- **Silicon**
  - Theoretical capacity of 4200 mAh/g \((\text{Li}_{15}\text{Si}_4)\)
  - Expands 400% upon lithiation
  - High irreversible capacity loss
  - High fade rate
  - Poor coulombic efficiency

- **Silicon carbon composites**
  - Carbon matrix absorbs expansion of the silicon and maintains electrical contact
  - Carbon matrix prevents direct electrolyte contact

![Estimates for cell specific energy and energy density](image-url)
In-House Anode Synthesis

- Silicon containing carbon gel microbeads
- Carbon fiber paper supported silicon containing carbon nanofoam
- Based on resorcinol-formaldehyde gel precursors containing nano-silicon
- Porous carbon matrix will absorb the expansion of the silicon and prevent direct silicon-electrolyte contact
- Makes use of traditional cost-effective laboratory techniques
Carbon Cryogel Anode Materials

Carbon-Silicon Microbeads

Carbon Nanofoam with Nano-Silicon Supported on Carbon Paper

Originally investigated by Hasegawa, Mukkai, Shiratu and Tamon *Carbon* 42, 2004 pp. 2573-2579

Carbon nanofoams are currently under investigation by J. Long at NRL for use in electrochemical capacitors and as electrode support materials.
Carbon-Silicon Microbeads

Mix microbeads with binder and cast onto copper foil current collector

- **Advantage**: Uses conventional manufacturing techniques
- **Disadvantage**: Requires heavy copper current collector

Carbon Nanofoam with Nano-Silicon Supported on Carbon Paper

- **Advantage**: “Stand Alone” electrode that does not require the use of a current collector (Lighter)
- **Disadvantage**: Would require development of new electrode and cell manufacturing techniques

Estimates for Component Weight Fraction in 30 Ah Cell

Anode copper current collector represents a significant weight fraction (8%)

Copper Foil  2g
• Not electrochemically active towards lithium

Carbon Paper  0.2 g
• Electrochemically active towards Li (250 mAh/g)
Carbon Microbead Testing

- Carbon microbeads were slurried with NaCMC
- 0.005” film cast onto copper foil
- Anodes placed in coin cells using lithium as the counter electrode
- Electrolyte: 1M LiPF$_6$ 1:1:1 ethylene carbonate, diethyl carbonate and dimethyl carbonate
- Cells formed at C/10 and cycled from 10mV to 1.5 V

Initial Results

- **Microbeads**
  - 425 mAh/g
  - Short of threshold value of 600 mAh/g and goal of 1000 mAh/g

- **Nanofoam**
  - Initial results showed 400 mAh/g at the electrode level
  - “Stand Alone” anode 100% active material
  - Determined to have a higher potential to meet or exceed goals
  - Decided to focus on development of the carbon nanofoam anodes

New Experiments

• Improve the performance of the Si-carbon nanofoams by addition of conductive additives or binders
  – Addition of graphite to resorcinol formaldehyde gel
  – Coat with polyaniline doped with LiPF$_6$

• New formation procedure
New Formation Procedure

- Very slow initial formation to 10 mV
- Replace taper charge with very low constant current to 10 mV

Nyquist Plot For Si-Carbon Nanofoam Anodes

- The nanofoam containing graphite has a lower impedance than the nanofoam which does not contain graphite.
- Samples coated with polyaniline/LiPF₆ show drastically lower impedances than those without the coating.
- The presence of graphite in combination with the polyaniline coating resulted in a higher impedance than that of a coated sample not containing graphite.
Conclusions

• A “Stand Alone” anode has been synthesized with specific capacities that meet and/or exceed the ETDP threshold value of 600 mAh/g and would likely compare favorably, with regard to specific capacity, at the electrode level to conventional coated anode materials

• “Stand Alone” carbon-silicon nanofoam anodes have the greater potential to address NASA goals

• “Stand Alone” carbon-silicon nanofoam anodes have the potential to significantly increase the specific energies (Wh/kg) for lithium-ion cells

• Addition of graphite to the silicon containing carbon nanofoam dramatically increases capacity

• Use of the conductive binder polyaniline doped with LiPF$_6$ dramatically increases capacity

• Very slow formation cycle is required to fully lithiate silicon
Future Work

• Investigate the use of various conductive additives
  – Graphites
  – Carbon Nanotubes
  – Carbon Nanofibers
• Investigate different binders or coatings
• Investigate different gel formulations
• Remove oxygen from matrix

Synthetic Conditions

- **Carbon-Silicon Microspheres**
  - Resorcinol-Formaldehyde containing 50 nm silicon is dispersed in a solution of cyclohexane and Span 80 surfactant
  - Sonicated
  - Stirred for two days at room temperature
  - Recovered and rinsed
  - Freeze dried in t-butanol
  - Pyrolyzed at 1000° C in argon

- **Carbon-Silicon Nanofoam**
  - Carbon fiber paper impregnated with resorcinol-formaldehyde gel containing 50 nm silicon particles
  - Sealed in plastic bags and placed between glass plates
  - Cured at room temperature for 2 days
  - Freeze dried in t-butanol
  - Pyrolyzed at 1000° C in argon
