**ABSTRACT**

Method and system for rapid and accurate determination of each of a sequence of unknown polymer components, such as nucleic acid components. A self-assembling monolayer of a selected substance is optionally provided on an interior surface of a pipette tip, and the interior surface is immersed in a selected liquid. A selected electrical field is impressed in a longitudinal or transverse direction at the tip, a polymer sequence is passed through the tip, and a change in an electrical current signal is measured as each polymer component passes through the tip. Each measured change in electrical current signals is compared with a database of reference signals, with each reference signal identified with a polymer component, to identify the unknown polymer component. The tip preferably has a pore inner diameter of no more than about 40 nm and is prepared by heating and pulling a very small section of a glass tubing.

Fig. 2B

Fig. 2C
Pass (unknown) polymer components sequentially through pore and measure ionic current signal for each polymer component. Compare each of sequence of measured ionic current change signals $CIC(t;meas)$ with reference change signals $CIC(t;ref;n)$ in a reference database. Assign each polymer component in unknown sequence to reference polymer component, based on signal comparison.

Fig. 3
Compute error $\varepsilon(n)$

Determine surviving collection $SC$ of reference change signals $CEC(t;\text{ref};n)$

Is $SC$ an empty set?

If YES

Assign special symbol (e.g., UNK) to corresponding unknown polymer component

If NO

Identify each reference change signal in the surviving collection $SC$

Identify at least one reference polymer component, whose corresponding reference signal is in $SC$, with the (unknown) polymer component

Fig. 4
Provide pipette with pore having a selected SAM positioned on pore interior surface

Immerse pore interior surface in a selected ionizable liquid

Impress transverse electrical field \( E(\text{trans}) \) across selected liquid in pore

Pass (unknown) polymer components through pore and measure electronic current signal for each polymer component as polymer passes through the pore

Compare each of sequence of measured electronic current change signals \( CEC(t;\text{meas}) \) with reference change signals \( CSC(t;\text{ref};n) \) in a reference database.

Assign each polymer component in unknown sequence to reference polymer component, based on signal comparison

BACKGROUND OF THE INVENTION

The invention described herein was made, in part, by an employee of the United States Government and may be manufactured and used by or for the Government for governmental purposes without the payment of any royalties thereon or therefor.

TECHNICAL FIELD

The present invention is a method and system for rapidly and accurately determining an ordered sequence of molecular units, such as bases in a nucleic acid, such as DNA or RNA, and for fabricating a nanopore system to facilitate the sequencing.

SUMMARY OF THE INVENTION

These needs are met by the invention, which provides a system and associated method that relies upon a pore at a pipette tip, having a pore diameter as small as 1-40 nm, preferably containing a selected alkali halide, ammonium compound (e.g., NH₄N(CH₃)₄), or a suitable organic compound or ionic inorganic compound (e.g., CaSO₄, Mg₆,(PO₄)₁₀). In one embodiment, a voltage difference is impressed, in a longitudinal direction or in a transverse direction, across an ionic liquid within the pore, and a varying ionic current through the pore, or a varying electron current across the pore (referred to collectively as an "electrical current") is measured in response to passage of each of an ordered sequence of polymer components, such as nucleotides in a nucleic acid or proteins, through the pore.

In one embodiment, the method includes steps of:
- providing a pipette having a longitudinal axis and having a tapered region having a pore with a selected pore diameter in a range of 1-40 nanometers (nm);
- providing a selected liquid in contact with an interior surface of the pore;
- impressing a selected voltage difference across the selected liquid within the pipette pore substantially parallel to the pipette longitudinal axis direction, and providing an ionic current value induced in the selected liquid, and passing an unknown polymer molecule, having a sequence of polymer components, through the pore, and determining a change in the ionic current signal induced by passage of each of the polymer components through the pore. In another embodiment, the voltage difference is impressed transversely, across the pore, and a transverse electronic current, induced in response to passage of each of the polymer components through the pore, is measured.

In another embodiment, a method for producing the pore includes steps of:
- heating a hollow cylinder of a selected pipette material, having first and second cylinder ends, having a longitudinal axis and having a selected initial inner diameter, with a selected heating source for at least one of first and second longitudinal locations for at least one of first and second selected time intervals;
- translating one of the first and second cylinder ends relative to the other, which transiently reduces ionic conductance through the pore, and
- allowing the hollow cylinder to separate into at least first and second pipettes and at least one of the first and second pipettes has a pore with a pore diameter in a range 1-40 nanometers (nm).

DESCRIPTION OF BEST MODES OF THE INVENTION

FIG. 1A illustrates one embodiment of apparatus for measurement of longitudinal ionic current in practicing the invention.

FIGS. 2A, 2B and 2C graphical views of typical sequences of ionic or electron current values measured with no polymer component present (2A), and in response to passage of a polymer component through a pore (2B, 2C).

FIGS. 3, 4 and 5 are flow charts illustrating procedures for practicing the invention according to two embodiments.

FIGS. 6A-6F graphically illustrate time variations that can be applied to an impressed voltage difference used in the invention.

FIGS. 7A and 7B illustrate formation of a pipette tip for use in the invention.
be octadecyltrichlorosilane (C₃₆H₇₃SiCl₃ or "OTS"), as dis-
provided with a self-assembling monolayer ("SAM") of a
interactions with a class of polymers of interest. The SAM
uncoated in practicing the invention. Preferably, the interior
interior surface of the pore 13p, and a second electrode 17B,
interactions with the different conformations. The conformational changes are
negatively charged carboxylate groups provides an attractive
voltage difference (e.g., —1054 mV to +654 mV) to the
hydrophilic carboxylate end groups. Cleavage of the car-
boxylate end groups provides a low density SAM of hydro-
permanent bonding, with a selected group of one or more
solution molecules that pass near the SAM array. A SAM may
be used to provide transient interactions with a polymer unit
passing through a nanopore and/or may be used to tailor the
effective longitudinal and/or transverse dimensions (diam-
eter, etc.) of a nanopore.

Formation of self-assembling monolayers on a gas or liq-
interface were first reported by Langmuir in J. Am. Chem.
Soc., vol. 39 (1917) 1848, and were first shown to be formable
on a solid surface by Blodgett, J. Am. Chem. Soc., vol. 57
(1935) 1007. Spontaneous formation of a SAM on a solid
substrate was first demonstrated by Bigelow, Pickett and Zis-
man, J. Colloid Interface Sci., vol. 1 (1946) 513 Chechik,
Crooks and Stirling, in “Reactions and Reactivity in Self-
Assembled Monolayers,” Advanced Materials, 2000, 1161-
1171, define a SAM as a monomolecular film of surfactant,
formed spontaneously on a substrate upon exposure to a
surfactant solution and provide a general review of use of
SAMs. A SAM may be disordered or close packed, depending
on the degree of wetting of the substrate surface. As noted by
Chechik et al, ibid, a SAM is ideally suited as a scaffold to
graft a polymer onto solid surfaces, because of the high den-
sity of functional groups, relatively small number of defects,
and a well defined structure. A molecule that is part of a SAM
may be terminated by various functional groups, such as OH
and amines.

A second example of an SAM is (16-Mercapto)hexade-
canoic acid (MHA) on a gold substrate, as studied and
371-374. MHA includes hydrophobic chains capped by
hydrophilic carboxylate end groups. Cleavage of the
carboxylate end groups provides a low density SAM of hydro-
phobic chains. Application of a small electrical potential or
voltage difference (e.g., —1054 mV ≤ V ≤ +654 mV) to the
negatively charged carboxylate groups provides an attractive
force that causes a conformation change in the hydrophobic
chains, whereby an all-trans conformation becomes partly
trans and partly gauche conformation, with substantial qual-
itative and quantitative changes in associated sum-frequency
generation (SFG) spectroscopic variations associated with
the different conformations. The conformational changes are
reversible so that removal of the applied electrical potential
causes a return to the relatively featureless SFG spectroscopic
variations associated with the original hydrophobic chain
conformations (all trans). Viewed from another perspective,
change in hydrophobic chain conformations associated with a
specific change, such as a variation in translocation associated
with passage of different polymer units through a nan-
opore in which a very thin layer of MHA on gold is provided,
would cause a measurable change in electrical current or
change in electrical potential (tens to hundreds of millivolts)
associated with passage of each (different) polymer unit.

In the absence of passage of a polymer component through
the pore, a steady ionic current through the pore (or electronic
current across the pore) will develop in response to impressing
a small voltage difference in a longitudinal (or transverse)
direction, as shown graphically in FIG. 2A.

An ordered sequence of polymer components, such as a
nucleic acid (e.g., DNA or RNA) is passed through the pore
13p, allowing development of a sequence of changing ionic
current values, as illustrated in FIGS. 2B and/or 2C. In FIG.
2B, passage of each polymer component through the pore 13p
is assumed to produce an approximately square wave signal,
having an approximately constant characteristic amplitude for a small time interval that corresponds to the time required for that polymer component to pass through the tip. In FIG. 2C, passage of each polymer unit through the pore 13p is assumed, more realistically, to produce a signal having a characteristic, time varying signal shape, a characteristic average amplitude and a characteristic shape parameter, for a small time interval that corresponds to the time required for that polymer component to pass through the tip.

Where one or more polymer components passes through the pore, translocation will cause the steady ionic current shown in FIG. 2A to change with time in response to passage of the polymer component through the pore and the accompanying translocation. If, for example, the polymer sequence is a nucleic acid, such as DNA (alternatively, RNA), each nucleotide will contain one of the four bases adenine (A), cytosine (C), guanine (G) and thymine (T) (alternatively, adenine, cytosine, guanine and uracil (U) for RNA). Ideally, each of the four bases (for DNA or for RNA) will produce a distinguishable change in ionic current signal as that nucleotide passes through the pipette tip, as suggested in FIG. 2B or FIG. 2C.

Under the influence of an applied voltage difference, negatively charged nucleotides or other polymer units are driven through the pore, and a polynucleotide strand can thus be threaded from one side of a lipid biolayer to the other. A steady electrical current that is present in the pore in the absence of a polymer unit is partly occluded during translocation. In principle, polymer units of different lengths can be distinguished from each other by translocation duration, and several homopolymers of different composition can be distinguished based on characteristic levels of electrical current reduction.

FIG. 3 is a flow chart of a procedure for practicing the invention. In step 31 of FIG. 3, a pipette, having a longitudinal axis and having a tapered tip with an associated pore having a selected pore minimum inner diameter d in a preferred range (e.g., d=1–40 nm) is provided, and a selected self-assembling monolayer (SAM) is optionally provided on some portion of the pore surface. In step 32, a selected first liquid containing ions is provided in the interior surface of the pore, preferably containing an alkali halide, ammonium compounds (e.g., NH₄, N(CH₃)₄⁺), or a suitable ionic organic compound or ionic inorganic compound (e.g., CsSO₄, Mg₃(PO₄)₂). More generally, the selected first liquid may be any solution that provides a concentration p of ions at least equal to a threshold value p(ion;thr), for example, p(ion;thr)=10⁷ M⁻¹. The liquid may include the polynucleotide or other polymer that is to be identified. In step 33, a voltage difference having a value in a range 4V–10,000 milliVolts is impressed on the liquid in the pore, in a direction substantially parallel to the pipette longitudinal axis. If the polymer has a net electrical charge, the polarity of the voltage difference is chosen to induce the polymer to pass through (or across) the pore. In step 34, ordered components in a polymer (unknown) are sequentially passed through the pore, and each of a sequence of changes in ionic current signals is measured, resulting in a sequence of measured values such as the sequences shown in FIG. 2B or FIG. 2C.

In step 35 (optional), the sequence of changes in measured ionic current signals CIC(t;meas) is compared, one-by-one or in consecutive groups, with reference change signals CIC(t;ref,n) numbered n=1, . . . , N(N≥2) in a reference signal database. Each reference change signal corresponds to a reference polymer component. In step 36 (optional), each polymer component (e.g., a nucleotide containing a particular base) in the unknown sequence is assigned to the reference polymer component having a reference ionic current change signal that is most similar, in some quantitative sense, to the measured (changes in) ionic current change signal. Optionally, steps 35 and 36 are performed off-line.

The signal comparison step 35 is optionally implemented as follows. The ionic current change signal CIC(t;meas) for the unknown polymer sequence is measured at a sequence of time values tₘ, producing a sequence of measured ionic current change values {CIC(tₘ;meas)}ₘ (m=1, . . . , M; M≥2). This sequence of measured ionic current change values is compared with a reference sequence (n) of ionic current change signal values {CIC(tₘ;ref,n)}ₘ, where τ(n) is a selected time shift that may vary with the reference number n being considered, by computing an error value

$$e(n) = \left( \sum_{m=1}^{M} w_m |CIC(t_m;meas) - CIC(t_{m+\tau(n);ref,n})|^p \right)^{1/p}$$

where {wₘ}ₘ is a selected sequence of non-negative weight values (at least one positive) and p is a selected positive number (e.g., p=1, 1.6 or 2). Reference ionic current change signals CIC(tₘ;ref,n) for which the error satisfies e(n)<e(thr), where e(thr) is a selected positive threshold value, are discarded and not considered further for this measured ionic current change value sequence {CIC(tₘ;meas)}ₘ. When at least one error value satisfies e(n)<e(thr), the “surviving collection”

SC={CIC(tₘ+\tau(n);ref,n)|e(n)<e(thr)}

of all reference signals with error values that satisfy the inequality e(n)<e(thr), are considered, and the reference ionic current change signal CIC(tₘ+\tau(n);ref,n) that provides the smallest error e(n) is assigned to the unknown polymer unit. When the surviving collection SC is an empty set, because no error value satisfies e(n)<e(thr), the system assigns a selected symbol, such as UNK, to this polymer unit.

The comparison procedure can be summarized in a flow chart in FIG. 4. In step 41, the error e(n), defined as in Eq. (1) or in another suitable manner, for each reference change signal CIC(tₘ+\tau(n);ref,n) in the database is computed. In step 42, the surviving collection SC of reference signals is determined. In step 43, the system determines if SC is an empty set. If the answer to the query in step 43 is “yes,” the system assigns a special symbol (e.g., UNK) to the corresponding measured ionic current signal in step 44, indicating that no reference change signal CIC(tₘ+\tau(n);ref,n) is sufficiently similar to the measured ionic current change signal. If the answer to the query in step 43 is “no” (SC is non-empty), the system identifies, in step 45, each reference change signal CIC(tₘ+\tau(n);ref,n) for which the corresponding error satisfies

$$e(n)=\min_{1≤n≤N} e(n)$$

In step 46, the system identifies at least one reference polymer component, for which the corresponding reference change signal CIC(tₘ+\tau(n);ref,n) is in the surviving collection SC, with the unknown polymer component whose signal was measured.

FIG. 5 is a flow chart of an alternate procedure for practicing the invention, using a transverse voltage difference. In step 51 of FIG. 5, a pipette, having a longitudinal axis and having a tapered tip with an associated pore having a selected pore minimum inner diameter d in a preferred range (e.g., d=1–40 nm) is provided, where a selected self-assembling monolayer is optionally provided on an interior surface of the pore. In step 52, the pore interior is provided with a selected...
pipette segments has a hollow core (a pore) with a pore  

71 separates into two pipette segments,  

range 0.1-2 cm or more, of a pipette 71 with a hollow core is  

be substantially monotonically increasing in time (FIG. 613),  

ponent having a reference electron current value that is most  

reference signal database. In step  

appropriate minimum inner diameter may be formed using  

glass, borosilicate glass or other suitable glass) having an  

locations, \(x_1, x_2, \ldots \), for one, two or more time inter-  

heated or otherwise receives substantial thermal energy, using  

trapezoidal variation, in which the middle  

is closest to the at least one determined ionic current  

closest to the at least one determined ionic current change  

region of a pipette (quartz glass, aluminosilicate  

glass, borosilicate glass or other suitable glass) having an  

appropriate minimum inner diameter may be formed using  

the following procedure, illustrated in FIGS. 6A,  

may be substantially uniform in time, as illustrated in FIG. 6A,  

may be substantially monotonically increasing in time (FIG. 6B),  

may be substantially monotonically decreasing in time (FIG. 6C),  

may vary substantially sinusoidally in time (FIG. 6E),  

may vary substantially trapezoidally in time (FIG. 6F),  

with temporal length segments \(t_1, t_2\) and \(t_3\), or may have another  

suitable time varying shape. The trapezoidal variation shown  

in FIG. 6F includes a triangular variation, in which the middle  

segment has length \(t_2-0\).  

A tip region of a pipette (quartz glass, aluminosilicate  

glass, borosilicate glass or other suitable glass) having an  

appropriate minimum inner diameter may be formed using  

the following procedure, illustrated in FIGS. 7A and 7B. A  

selected middle region 73, having a preferred length \(L_{11}\) in a  

range 0.1-2 cm or more, of a pipette 71 with a hollow core is  

heated or otherwise receives substantial thermal energy, using  

a laser, infrared source or a heated metal filament 75 and  

(optional) associated focusing system 76, at one or more  

locations, \(x-x_1, x-x_2, \ldots \), etc., for one, two or more time intervals,  

of length \(\Delta t_1, \Delta t_2, \ldots \). The time intervals may partly or  

wholly overlap or may be isolated from each other. As the  

heating or irradiation continues, one or both of first and  

second ends, 77-1 and 77-2, of the pipette is pulled with a  

selected force \(F\), optionally \(10^1-10^4\) dynes or more, or at a  

selected displacement rate, \(v\) of a few mm/sec, so that the first  

and second ends are displaced relative to each other. The  

pipette 71 separates into two pipette segments, 71-1 and 71-2,  

in the (last) heating cycle, and at least one of the two resulting  

pipette segments has a hollow core (a pore) with a pore  

minimum inner diameter \(d_{\text{min}}\). Tip parameters (thickness,  

nanopore diameter, nanopore length, etc.) can be partly con-  

trolled by appropriate choice of one or more of the parameters  

heating rate, \(L_{11}, \Delta t_{\text{ irr}}, F\) and/or \(v\).  

Suitable applications of the invention, using ionic current or  
electronic current, include the following: (1) counting of  
genomic or non-genomic fragments, by identification of a  
first end and/or a second end of each fragment that passes  
through a nanopore; (2) identification of locations of single  
strand segments and double strand segments in a “mixed”  
DNA sequence passing through a nanopore; (3) discrimination  
between single strands and double strands of DNA passing  
through a nanopore; and (4) identification of individual  
nucleotides in single strand DNA passing through a nanop-  
ore; (5) identification of corresponding base pairs (e.g.,  
eytosine-guanine, adenine-thymine and adenine-uracil) in a  
double strand DNA or RNA passing through a nanopore, and  
(6) estimation of polymer component length by correlation  
with length of time interval for translocation.  

What is claimed is:  

1. A method for obtaining a reading of a sequence of  

components in a polymer molecule, the method comprising:  

providing a pipette having a longitudinal axis and having a  
tapered region and having a pore with a selected pore  
diameter in a range of 1-40 nanometers (nm);  

providing a selected liquid in contact with an interior sur-  
fase of the pore;  

impressing a selected voltage difference across the selected  
liquid within the pipette pore substantially parallel to the  
pipette longitudinal axis direction, and providing an  
ionic current value induced in the selected liquid;  

passing a polymer molecule, having a sequence of two or  
more polymer components, through the pore, and deter-  
mining a change in the ionic current signal induced by  
passage of each of the polymer components through the  
pore;  

comparing each of the sequence of changes in ionic current  
signals with each of \(N\) reference ionic current change  
signals (\(N>2\)), with each reference ionic current change  
signal corresponding to a reference polymer component  
drawn from a reference group of polymer components;  

and  

for at least one of the determined changes in ionic current  
signals for one of the polymer components, identifying  
the polymer component with the reference polymer  
component whose reference ionic current change signal  
is closest to the at least one determined ionic current change  
signal.  

2. The method of claim 1, further comprising providing a  
self-assembling monolayer of a selected substance on a  
selected portion of said interior surface of said pore.  

3. The method of claim 2, further comprising choosing said  
self-assembling monolayer to include at least one of: (i) octa-  
decyltrichlorosilane on glass and (ii) (16-Mercapto)hexade-  
canonic acid on a gold substrate.  

4. The method of claim 1, further comprising choosing said  
polymer sequence to be a nucleic acid sequence including  
the bases adenine, cytosine and guanine and at least one of the  
bases thymine and uracil.  

5. The method of claim 1, further comprising selecting  
material for said pipette from a group of materials including  
quartz glass, aluminosilicate glass and borosilicate glass.  

6. The method of claim 1, further comprising choosing said  
selected liquid to include at least one of an alkali halide, an  
ammonium compound, an ionic organic compound and an  
ionic inorganic compound.  

7. The method of claim 1, further comprising providing a  
selected second liquid in contact with a portion of a surface of  
said pipette not including said interior surface of said pore.
8. The method of claim 7, further comprising choosing said second liquid to be substantially the same as said selected first liquid.

9. The method of claim 7, further comprising choosing said second liquid to be different from said selected first liquid.

10. The method of claim 1, wherein said process of identifying said polymer component with said reference polymer component whose reference ionic current signal is closest to said at least one determined ionic current signal comprises:

(i) measuring a value $CIC(t_m; \text{meas})$ of said determined ionic current change signal at each of a sequence of times $t=t_m$, $(m=1, \ldots , M; M \geq 1)$;

(ii) forming an error value, defined as

$$
(n) = \left( \sum_{m=1}^{M} w_m (CIC(t_m; \text{meas}) - CIC(t_m; + \epsilon(n); ref); n)^p \right)^{1/p},
$$

between said determined ionic current change signal value and a corresponding reference ionic current change signal value, for each of N reference ionic current change signals $CIC(t_{m*}; + \epsilon(n); ref); n)$, numbered $n=1, \ldots , N(N \geq 2)$, where $\{w_m\}$ is a set of selected non-negative weight values, $\epsilon(n)$ is a selected time shift value and $p$ is a selected positive number; and

(iii) when at least one reference ionic current signal, numbered $n'$, satisfies $\epsilon(n') \leq \epsilon(\text{thr})$, where $\epsilon(\text{thr})$ is a selected threshold value, identifying at least one reference polymer component, numbered $n''$, with said polymer component, where $\epsilon(n'') = \min_{1 \leq n \leq N} \epsilon(n)$.

11. The method of claim 1, further comprising passing said polymer sequence through said tapered tip of said pipette at an average rate in a range of 10-1000 polymer components per millisecond.

12. The method of claim 1, further comprising selecting said voltage difference from a group of time-dependent differences including a difference that (i) is substantially uniform in time; (ii) increases substantially monotonically with time; (iii) decreases substantially monotonically with time; (iv) is substantially a step function in time; (v) varies substantially sinusoidally with time; and (vi) varies substantially trapezoidally with time.

13. A method for obtaining a reading of a sequence of components in a polymer molecule, the method comprising:

providing a pipette having a longitudinal axis and having a tapered region and having a pore with a selected pore diameter in a range of 1-40 nanometers (nm), where a self-assembling monolayer of a selected substance is provided on an interior surface of the pore; providing a selected liquid in contact with an interior surface of the pore; impressing a selected voltage difference across the selected liquid within the pipette pore transverse to the pipette longitudinal axis direction, and providing an electronic current value induced in the selected liquid; passing a polymer molecule, having a sequence of two or more polymer components, through the pore, and determining a change in the electronic current signal induced by passage of each of the polymer components through the pore.

comparing each of the sequence of changes in electronic current signals with each of N reference electronic current change signals $(n \geq 2)$, with each reference electronic current change signal corresponding to a reference polymer component drawn from a reference group of polymer components; and

for at least one of the determined changes in electronic current signals for one of the polymer components, identifying the polymer component with the reference polymer component whose reference electronic current change signal is closest to the at least one determined electronic current change signal.

14. The method of claim 13, wherein where a self-assembling monolayer of a selected substance is provided on a selected portion of said interior surface of said pore.

15. The method of claim 14, further comprising choosing said self-assembling monolayer to include at least one of: (i) octadecyltrichlorosilane on glass and (ii) (16-Mercapto) hexadecanoic acid on a gold substrate.

16. The method of claim 13, further comprising choosing said polymer sequence to be a nucleic acid sequence including the bases adenine, cytosine and guanine and at least one of the bases thymine and uracil.

17. The method of claim 13, further comprising selecting material for said pipette from a group of materials including quartz glass, aluminosilicate glass and borosilicate glass.

18. The method of claim 13, further comprising choosing said selected liquid to include at least one of an alkali halide, an alkaline halide, a nitrate and a sulfate.

19. The method of claim 13, further comprising providing a selected second liquid in contact with a portion of a surface of said pipette not including said interior surface of said pore.

20. The method of claim 19, further comprising choosing said second liquid to be substantially the same as said selected first liquid.

21. The method of claim 19, further comprising choosing said second liquid to be different from said selected first liquid.

22. The method of claim 13, wherein said process of identifying said polymer component with said reference polymer component whose reference electronic current change signal is closest to said at least one determined electronic current signal comprises:

(i) measuring a value $CEC(t_m; \text{meas})$ of said determined electronic current change signal at each of a sequence of times $t=t_m$, $(m=1, \ldots , M; M \geq 1)$;

(ii) forming an error value, defined as

$$
\epsilon(n) = \left( \sum_{m=1}^{M} w_m (CEC(t_m; \text{meas}) - CEC(t_m; + \epsilon(n); ref); n)^p \right)^{1/p},
$$

between said determined electronic current change signal value and a corresponding reference electronic current change signal value, for each of N reference electronic current change signals $CEC(t_{m*}; + \epsilon(n); ref); n)$, numbered $n=1, \ldots , N(N \geq 2)$, where $\{w_m\}$ is a set of selected non-negative weight values, $\epsilon(n)$ is a selected time shift value and $p$ is a selected positive number; and

(iii) when at least one reference ionic current signal, numbered $n'$, satisfies $\epsilon(n') \leq \epsilon(\text{thr})$, where $\epsilon(\text{thr})$ is a selected threshold value, identifying at least one reference polymer component, numbered $n''$, with said polymer component, where $\epsilon(n'') = \min_{1 \leq n \leq N} \epsilon(n)$.

23. The method of claim 13, further comprising passing said polymer sequence through said tapered tip of said pipette at an average rate in a range of 10-1000 polymer components per millisecond.
24. The method of claim 13, further comprising selecting said voltage difference from a group of time-dependent differences including a difference that (i) is substantially uniform in time; (ii) increases substantially monotonically with time; (iii) decreases substantially monotonically with time; (iv) is substantially a step function in time; (v) varies substantially sinusoidally with time; and (vi) varies substantially trapezoidally with time.
