Dehydrating and Sterilizing Wastes Using Supercritical CO₂

Lyndon B. Johnson Space Center, Houston, Texas

A relatively low-temperature process for dehydrating and sterilizing biohazardous wastes in an enclosed life-support system exploits (1) the superior mass-transport properties of supercritical fluids in general and (2) the demonstrated sterilizing property of supercritical CO₂ in particular. The wastes to be treated are placed in a chamber. Liquid CO₂, drawn from storage at a pressure of 850 psi (≈5.9 MPa) and temperature of 0 °C, is compressed to pressure of 2 kpsi (≈14 MPa) and made to flow into the chamber. The compression raises the temperature to 10 °C. The chamber and its contents are then further heated to 40 °C, putting the CO₂ into a supercritical state, in which it kills microorganisms in the chamber. Carrying dissolved water, the CO₂ leaves the chamber through a back-pressure regulator, through which it is expanded back to the storage pressure. The expanded CO₂ is refrigerated to extract the dissolved water as ice, and is then returned to the storage tank at 0 °C.
