ings. Also, the overall efficiency of the suspension system improves with speed, whereas the performance of conventional bearings degrades as speed increases.

This innovation will greatly advance aircraft electrical power systems with the development of an efficient, reliable, maintenance-free, and safe electrical generation system. The use of magnetic suspension minimizes concerns associated with traditional bearings, such as active lubrication, contact wear, and limited rotational speed. The ducted hardware can translate into improved efficiency and reliability. The concept lends itself to a configuration in which the units can be used individually or clustered for distributed power applications. In addition, the concept can be readily scaled into a variety of sizes for specified
dered for distributed power applications.

A prototype stator and assembly and rotor have been designed and developed to study and evaluate subsystem level characteristics of the generation and levitation systems in a laboratory environment, and to verify theoretical predictions. The test setup has been used to measure successfully the flux density emanating from the rotor, the induced current in the stator winding as the rotor is driven at various speeds, the associated induced current, and the generated repulsive force. Experimental results correlate well with performance characteristics predicted using the derived theoretical equations. The goal of the final design is a self-contained suspension and electrical generation system free from mechanical couplings. The use of magnetic suspension minimizes concerns associated with traditional bearings, such as active lubrication and limited rotational speeds.

Compact, Two-Sided Structural Cold Plate Configuration

Lyndon B. Johnson Space Center, Houston, Texas

In two-sided structural cold plates, typically there is a structural member, such as a honeycomb panel, that provides the structural strength for the cold plates that cool equipment. The cold plates are located on either side of the structural member and thus need to have the cooling fluid supplied to them. One method of accomplishing this is to route the inlet and outlet tubing to both sides of the structural member. Another method might be to supply the inlet to one side and the outlet to the other. With the latter method, an external feature such as a hose, tube, or manifold must be incorporated to pass the fluid from one side of the structural member to the other. Although this is a more compact design than the first option, since it eliminates the need for a dedicated supply and return line to each side of the structural member, it still poses problems, as these external features can be easily damaged and are now new areas for potential fluid leakage.

This invention eliminates the need for an external feature and instead incorporates the feature internally to the structural member. This is accomplished by utilizing a threaded insert that not only connects the cold plate to the structural member, but also allows the cooling fluid to flow through it into the structural member, and then to the cold plate on the opposite side. The insert also employs a cap that acts as a cover to seal the open area needed to install the insert. There are multiple options for location of O-ring style seals, as well as the option to use adhesive for redundant sealing. Another option is to weld the cap to the cold plate after its installation, thus making it an integral part of the structural member. This new configuration allows the fluid to pass from one cold plate to the other without any exposed external features.

AN Fitting Reconditioning Tool

John F. Kennedy Space Center, Florida

A tool was developed to repair or replace AN fittings on the shuttle external tank (ET). (The AN thread is a type of fitting used to connect flexible hoses and rigid metal tubing that carry fluid. It is a U.S. military-derived specification agreed upon by the Army and Navy, hence AN.) The tool is used on a drill and is guided by a pilot shaft that follows the inside bore. The cutting edge of the tool is a standard-size replaceable insert. In the typical Post Launch Maintenance/Repair process for the AN fittings, the six fittings are removed from the ET’s GUCP (ground umbilical carrier plate) for reconditioning. The fittings are inspected for damage to the sealing surface per stan-
