Cryo-Etched Black Silicon for Use as Optical Black

NASA’s Jet Propulsion Laboratory, Pasadena, California

Stray light reflected from the surface of imaging spectrometer components — in particular, the spectrometer slit — degrade the image quality. A technique has been developed for rapid, uniform, and cost-effective black silicon formation based on inductively coupled plasma (ICP) etching at cryogenic temperatures. Recent measurements show less than 1-percent total reflectance from 350–2,500 nm of doped black silicon formed in this way, making it an excellent option for texturing of component surfaces for reduction of stray light.

Oxygen combines with SF<sub>6</sub> + Si etch byproducts to form a passivation layer atop the Si when the etch is performed at cryogenic temperatures. Excess flow of oxygen results in micromasking and the formation of black silicon. The process is repeatable and reliable, and provides control over etch depth and sidewall profile. Density of the needles can be controlled to some extent.

Regions to be textured can be patterned lithographically. Adhesion is not an issue as the nanotips are part of the underlying substrate. This is in contrast to surface growth/deposition techniques such as carbon nanotubes (CNTs).

The black Si surface is compatible with wet processing, including processing with solvents, the textured surface is completely inorganic, and it does not outgas.

In radiometry applications, optical absorbers are often constructed using “gold black” or CNTs. This black silicon technology is an improvement for these types of applications.

Advanced CO<sub>2</sub> Removal and Reduction System

Lyndon B. Johnson Space Center, Houston, Texas

An advanced system for removing CO<sub>2</sub> and H<sub>2</sub>O from cabin air, reducing the CO<sub>2</sub>, and returning the resulting O<sub>2</sub> to the air is less massive than a prior system that includes two assemblies — one for removal and one for reduction. Also, in this system, unlike in the prior system, there is no need to compress and temporarily store CO<sub>2</sub>. In this present system, removal and reduction take place within a single assembly, wherein removal is effected by use of an alkali sorbent and reduction is effected using a supply of H<sub>2</sub> and Ru catalyst, by means of the Sabatier reaction, which is CO<sub>2</sub> + 4H<sub>2</sub> → CH<sub>4</sub> + O<sub>2</sub>. The assembly contains two fixed-bed reactors operating in alternation: At first, air is blown through the first bed, which absorbs CO<sub>2</sub> and H<sub>2</sub>O. Once the first bed is saturated with CO<sub>2</sub> and H<sub>2</sub>O, the flow of air is diverted through the second bed and the first bed is regenerated by supplying it with H<sub>2</sub> for the Sabatier reaction. Initially, the H<sub>2</sub> is heated to provide heat for the regeneration reaction, which is endothermic. In the later stages of regeneration, the Sabatier reaction, which is exothermic, supplies the heat for regeneration.

Correcting Thermal Deformations in an Active Composite Reflector

Composite actuators can be embedded into an easy-to-manufacture flat surface.

NASA’s Jet Propulsion Laboratory, Pasadena, California

Large, high-precision composite reflectors for future space missions are costly to manufacture, and heavy. An active composite reflector capable of adjusting shape in situ to maintain required tolerances can be lighter and cheaper to manufacture.

An active composite reflector testbed was developed that uses an array of piezoelectric composite actuators embedded in the back face sheet of a 0.8-m reflector panel. Each individually addressable actuator can be commanded from -500 to +1,500 V, and the flatness of the panel can be controlled to tolerances of 100 nm. Measuring the surface flatness at this resolution required the use of a speckle holography interferometer system in the Precision Environmental Test Enclosure (PETE) at JPL.

The existing testbed combines the PETE for test environment stability, the speckle holography system for measuring out-of-plane deformations, the active panel including an array of individu-
