
Introduction: The currently operating Dawn mission shows asteroid 4 Vesta to be an extensively cratered body, with craters in a variety of morphologies and preservation states. The crater size-frequency distribution for Vesta, modeled using the lunar chronology and scaled to impact frequencies modeled for Vesta, shows that both the north and south pole areas are ancient in age [1].

We have in our meteorite collection products from 4 Vesta in the form of the HED (howardite, eucrite, diogenite) meteorites. The HED parent body globally differentiated and fully crystallized by ~4.56 Ga; subsequently, the eucrites were brecciated and heated by large impacts into the parent body surface, reflected in their disturbance ages [2, 3].

Dawn images have also shown that Vesta is covered with a well-developed regolith that is spectrally similar to howardite meteorites [4, 5]. Howardites are polymict regolith breccias made up mostly of clasts of eucrites and diogenites, but which also contain clasts formed by impact into the regolith. Impact-melt clast ages from howardites extend our knowledge of the impact history of Vesta, expanding on eucrite disturbance ages and helping give absolute age context to the observed crater-counts on Vesta.

Howardite Impact-melt Clasts: We characterized texture, bulk composition, mineralogy, and ages of individual clasts within howardites EET 87513, QUE 94200, GRO 95574 and QUE 97001 in 100-μm thick, polished sections. Several clasts proved to be eucritic, but most were impact-melt clasts having a fine-grained, microporphyritic groundmass containing anhedral, relic mineral grains. The groundmass is usually too fine-grained to directly analyze the plagioclase or mafic portions. The relic clasts are dominated by plagioclase and pyroxene, with minor olivine, chromite, and other minerals. Pyroxene grains are typically homogeneous and unexsolved. Plagioclase has a wide range of compositions between typical eucrites and diogenites. Several clasts have symplectic textures with glassy areas. In these clasts, plagioclase can be significantly K-rich. The impact-melt clasts have bulk compositions ranging in between the eucrites and diogenites (Fig. 1), consistent with their interpretation as impact melt rocks made up of varying contributions of Vesta’s two main lithologies.

Samples were irradiated and step-heated using a CO₂ laser. Data were corrected for system blanks, decay time, and reactor-induced interferences. Resolution of cosmogenic and trapped argon components was attempted following [6, 7], but cosmogenic 36Ar is not well-correlated with any specific component in these samples [3], so this correction was not pursued further. Most ages are reported from isochrons, which do not assume a trapped component; those with plateau ages assume a trapped contribution of zero and are therefore upper limits. Table 1 shows the new howardite ages, including the first impact-melt ages from HED meteorites. All of the new impact-melt ages fall between 4.0 and 3.5 Ga, and most are distinct from one another, meaning they sample different impact events on the surface of 4 Vesta.

Discussion: Our new impact-melt ages fall well within the age distribution of all HED impact-reset rocks, which features a short, intense spike at 4.48 Ga followed by a period of relative quiescence, then a ramping up of impact-reset ages between about 4.0 and 3.5 Ga.

Fig. 1. The bulk composition of the impact-melt clasts is intermediate between eucrites and diogenites.
3.5 Ga (Fig. 2). Bogard and Garrison [8] suggested that the early spike, largely contributed by unbrecciated eucrites, represents a single large impact into Vesta that caused widespread resetting and may have formed a secondary parent body, protecting the unbrecciated eucrites from further processing in the Vesta regolith.

Impact-reset ages in the HEDs are consistent with a quiescent period in the main belt, followed by increased activity in the period of the late heavy bombardment. However, this seems at odds with the observed crater distribution on Vesta, which shows a range of ages rather than a single resurfacing event. Rather, we suggest that the age distribution of HED meteorites only incompletely records the impact history of Vesta, because of the difficulty of resetting rock ages by collisions in the main belt.

Reset of argon-based ages is a diffusion-controlled process, where a combination of temperature and time is required to lose daughter Ar from the crystal lattice sites originally occupied by K cations. Eucrites (and howardites) contain K (and therefore Ar) primarily in pyroxene and plagioclase. Recent work on diffusion coefficients in these minerals [9, 10] permit a quick look at closure temperatures and diffusion rates in these minerals, which in turn constrains the conditions required to reset the age of these rocks.

Fig. 3 shows the time required to completely diffuse Ar (fully reset) through each mineral across different length scales. At elevated temperatures, plagioclase can diffuse Ar fairly rapidly, but pyroxene requires a very high temperature to fully reset, even on the single grain scale. At higher temperatures, complete melting occurs, which readily allows Ar diffusion and age reset. Temperatures in the range that enable significant diffusion over timescales of 1-100 years (fast cooling of a post-impact blanket) are relatively high, in the range of 1000°C.

Whether temperatures reach this high in the target rock is a strong function of the impact velocity. Typical impact velocities between objects in the main belt is about 5 km [11], which imparts far too little energy to raise the temperature of the target material above the closure temperature of typical eucrite minerals (300-400°C for plagioclase, 600-700°C for pyroxene). Of course, there is a velocity distribution, where some small fraction of impactors may achieve this high velocity, but these must be comparatively rare.

Our new impact-melt analyses deepen this story. In order to melt material on the surface of Vesta, an impact must have higher velocity still. The tail of the main belt velocity distribution doesn’t stretch far enough to enable so much melt from so many different impact events spaced so closely in time. Therefore, we contend that these impact-melt clasts, and probably most of the impacts in this period, must be the result of highly velocitous impacts, possibly from an excited main belt (E-Belt) [12] or originating outside the main belt, as in the cometary flux of the Nice model [13]. Either way, howardite impact-melt clast ages record an unusual period of bombardment in the inner solar system beginning at around 4.0 Ga.

The Vestal Cataclysm

The 4 Vesta rock record

- HEDs = Howardites, Eucrites, Diogenites, largest achondrite group, spectrally linked to Vesta
- The HED parent body globally differentiated and fully crystallized around 4.56 Ga (Lugmair and Shukolyukov, 1998)
  - Eucrites – basaltic crust
  - Diogenites – cumulate mantle
- Dawn shows that Vesta is extensively cratered and covered with a well-developed regolith spectrally similar to howardites
  - Howardites - polymict regolith breccias
- Regolith brecciation and heating by impacts should be reflected in HED disturbance ages
Disturbance ages in HEDs

- Age distribution of all HED impact-reset rocks (Bogard and Garrison, 1993, 2003)
  - A short, intense spike at 4.48 Ga,
  - Followed by a period of relative quiescence, then
  - Ramping up between about 4.0 and 3.5 Ga

Impact-melt clasts in howardites

- Most dated rocks and clasts are eucrites - heated and degassed without fundamentally changing their character
- Impact-melt clasts are less common, smaller, but possibly more likely to have been fully degassed, and largely unstudied
- Characterized texture, bulk composition, mineralogy, and $^{40}\text{Ar}-^{39}\text{Ar}$ ages of 37 individual clasts within howardites EET 87513, QUE 94200, GRO 95574 and QUE 97001 in 100-µm thick, polished sections
Clast textures

- A01, eucritic clast with a classic basaltic texture consisting of blocky feldspar (gray) and pyroxene (white)
- D01, acicular pyroxene and plagioclase in an impact-melt clast
- C07, also a microporphyritic impact-melt clast, but with a higher proportion of relic clasts

Clast compositions

- Impact-melt clasts have a composition intermediate between eucrites and diogenites
- Clasts are not a previously-unknown evolved basaltic product (sorry Duck)
\[ 40 \text{Ar}^{39} \text{Ar} \text{ data} \]

- Not all clasts produced good Ar-Ar data (not enough heating steps, discordant “plateaus”, etc.)
- Data examined using plateau plots, isochrons, and inverse isochrons, most conservative interpretations chosen

\[ \text{New impact-melt ages (11)} \]
\[ \text{predominantly} \]
\[ \text{3.6-3.8 Ga} \]
\[ \text{Fall well within the age distribution of all HED impact-reset rocks} \]

\[ \text{All HED reset ages} \]
\[ \text{New Howardite clasts} \]
Reseting material on Vesta

- Significant diffusion in 100-10,000 y (cooling of an impact blanket) takes >800°C
- Typical impact \( v \) between objects in the main belt (5 km/s) imparts too little energy to raise \( T \) more than a few hundred °C

![Diffusion coefficients in plagioclase and pyroxene (Cassata et al. 2008, 2010; Weirich et al. 2012)](image)

Melting material on Vesta

- Melting material requires even more energy = higher relative \( v \)
- Main belt velocity distribution unlikely to explain so much melt from so many different impact events spaced so closely in time
- Howardite impact-melt clasts, and therefore probably most of the Vesta impacts in this period, must be the result of highly velocitous impacts
  - Excited main belt (E-Belt) (Bottke et al. 2010)?
  - Cometary flux of the Nice model (Gomes et al. 2005)?
Impact-melt clasts in howardites are rare but present — formed by that impact-mixing of other 4 Vesta regolith
- Textures demonstrate they were melted and recrystallized
- Compositions demonstrate they are a mixture of eucrites and diogenites

Impact-melt clast ages range between 3.5 and 4.0 Ga
- Coincident with most Ar-reset ages of eucrites and eucritic clasts

Forming impact melt on the surface of Vesta well after solar system accretion demands IOUVs (impacts of unusual velocity)

Vestal Cataclysm = A period of bombardment beginning around 4.0 (and extending to 3.5 Ga) caused by a distinct, high velocity population of impactors

Demonstrates the power of synergy between samples, sample ages, and dynamical models (thanks NLSI!)
