Introduction
NBL EVA Training

- Each training run is approximately 6 hrs in duration
- Training EVA: Spaceflight EVA ~6-10:1
- Suit pressurized to 4.3 psi/100% O₂
- The goal of our study was to obtain objective data to support subjective or anecdotal reports
Background

• 2003 NASA EMU Shoulder Injury Tiger Team Report¹

• “Major” shoulder injuries occur secondary to
  – Limitations to normal shoulder mechanics in the planar HUT
  – Inverted body positions
  – Performing overhead tasks
  – Use of heavy tools
  – Repetitive motions
  – Frequent NBL runs

• Shoulder injury mishap occurred during suited NBL training
  – crewmember experienced a shoulder strain during an NBL run
  – related to wearing a stainless steel waist bearing in place of the standard aluminum waist bearing
Background

Issues addressed in the NBL Safety report

1. Are there a lot of astronaut injuries at the NBL?
2. Are there injuries and close calls at the NBL that go unreported and undocumented?
3. Have we normalized the signs of an impending injury due to the inherent issues with the suit design and the NBL environment? That is, have we just accepted the hazards associated the suit design and the NBL environment.
4. Are the NBL injuries preventable?
5. Does the use of EMU stainless steel waist rings vs. aluminum waist rings cause injuries in the NBL?
6. Are the configuration control and configuration change processes allowing unapproved EMU and Tool configurations to be used in the NBL?
7. Is medical care at the NBL “state of the art” especially in the area of preventative measures?
8. Is the EMU planar shoulder design the root cause of most of the NBL shoulder injuries?
9. Are heavy tools (not neutrally buoyant) a contributing factor to shoulder injuries in the NBL?
Background

• Current NBL Safety team assessed the implementation status of all the recommendations from 2003 Shoulder Injury Tiger Team report
  – “All actions and recommendations were implemented effectively and have had positive results with respect to safety at the NBL”
  – Key Items not implemented:
    1. EMU Planar Shoulder not redesigned
    2. Limited tracking of crew physical training due to multiplicity of training venues
NBL/EMU-Related Shoulder Injury

• Planar HUT when compared to the Pivoted
  – Restricts range of shoulder motion, placing increased strain on the rotator cuff muscles
  – Fixes the shoulder in internal rotation predisposing the shoulder to impingement

• The injuries sustained are chronic, cumulative and in time, many cases require surgery
Pivoted vs. Planar HUT

Helmet Disconnect – Same Size

Scye Openings
Pivoted – 2 Sizes
Planar – 1 Size

HUT Side BSC
Pivoted – 3 Sizes
Planar – 1 Size

Pivoted HUT

Planar HUT
Suited Shoulder ROM

- Planar HUT design limitations in shoulder ROM
  - Abduction ~60°-90°
  - Flexion ~90°
  - Internal rotation ~40°
  - External rotation ~35°
Shoulder Range of Motion (ROM)  
Pivoted vs. Planar HUT
Suit Donning and Doffing

Shoulder Impingement & Rotator Cuff Tear
Un-suited vs. suited (planar HUT) shoulder strength related to normal scapulo-thoracic mechanics*

*Data used with permission from M. Guilliams, S. Rajulu 2011.
Study Assumptions

- After 1997, all EVA training in the NBL was performed in the planar HUT.
- After 1995, all ASCANs participated in EVA training in NBL.
- Prior to 1995, ASCANs may or may not have participated in EVA NBL training.
- Following Challenger in 1986, EVA training occurred in the WETF but no spaceflight EVAs took place until 1991.
- EVA training hours in the NBL rose dramatically in the late 1990's with the ISS construction.

- Each NBL training run is ~6 hrs in duration.
- The training run ratio to spaceflight EVA is approximately 11.6.

- The study has all the known shoulder surgical cases in NASA astronauts.

---

Methods

• US astronaut EVA training data and spacesuit design employed were analyzed from the NBL database from 1995-2011.
  – Shoulder surgery data was acquired from the medical record database
  – causal mechanisms were obtained from personal interviews
  – analysis of the individual HUT designs was performed as it related to normal shoulder biomechanics
Shoulder Injuries Requiring Surgical Repair

- 330 US astronauts
  - 103 have performed at least one space flight EVA (prior to shoulder surgery)

- 23 astronauts have had shoulder surgery
  - 25 surgeries
  - two astronauts have had surgery on both shoulders

- Excludes shoulder *injuries*
  - Including prior history of training-related shoulder surgery
  - Sprains and strains
  - Impingement
  - Pain
Shoulder Surgeries

• Of the 25 astronauts who have had surgery
  – 12 describe an event or mechanism of injury related to training in the planar HUT
  – 12 deny any specific event that can be attributed to donning, doffing or training in the EMU
  – 1 remain outstanding or unknown as of 12-Apr-12
## Individual Shoulder Surgery Cases

</tbody>
</table>

- P = 0.08 (Fisher’s exact)
- Not significant assuming 0.05 level of significance, but it’s suggestive of a real difference
  - We just have a very small sample size
Caveats to training data

• After 1997, astronauts would train in the planar HUT until they got injured, then would switch to the pivoted HUT.
Initial Assessment

• Planar suits first used for space flight EVAs on STS-82
  – Only Shuttle data used

• EVAs pre STS-82 (<1997)
  – Pivoted suit

• EVAs post STS-82 (>1997)
  – Planar suit

• 88 astronauts with US space flight EVAs
  – Excludes Orlan only
  – Excludes non-Shuttle EVAs
  – Excludes EVAs post-surgery (first surgery)
Surgeries by Number of EVAs

- Not statistically significant but a trend emerged
- Astronauts who performed ≥ 5 EVAs were 2.1 times more likely to have had shoulder surgery compared with astronauts who performed 1 EVA

<table>

- $P = 0.59$ (Trend)
EVA Training Data

• Training data became available
  – June 1995 to present- electronic
    • NBL became functional in Oct. 1996
  – No data available for 176 astronauts
  – Older records in paper format are not included in this data set

• Clarification that training occurs in both suits for most astronauts

• Number of EVA training runs
  – Pivoted
  – Planar
  – Duration of training runs not included

</tbody>
</table>

- **Fisher:** $P=0.20$
- **Trend:** $P<0.05$

Astronauts who had >92 total training runs (in either suit) were about 5.9 times more likely to have had shoulder surgery compared with astronauts who have had 0-9 training runs.
Planned EVAs in Future

• For ISS missions, ~8 EVAs planned per year
• Numbers of crew members limited
• CONUS training time for US crewmembers limited
  – i.e. training “density” may still be an issue secondary to international travel, other duties, etc
Preliminary Summary

• For spaceflight EVA
  – Astronauts who performed ≥ 5 EVAs were 2.1 times more likely to have had shoulder surgery compared with astronauts who performed 1 EVA

• For training EVA
  – The proportions of astronauts who attribute their injury to the planar HUT was significantly different across the 3 groups (Pivoted vs. Planar vs. Both).
    • Astronauts who trained ONLY in the pivoted suit were less likely to attribute the injury to the pivoted HUT compared with astronauts who trained ONLY in the planar or in both suits.
  – Astronauts who had >92 total training runs (in either suit) were about 5.9 times more likely to have had shoulder surgery compared with astronauts who have had 0-9 training runs
    • Regardless of the HUT design, the likelihood of shoulder sx increased from 2.7% (0-9 runs) to 5% (10-91 runs) to 15.8% (>92 runs)
1. There are *multiple* factors associated with the mechanism of injury that leads to shoulder injury requiring surgical repair
   - E.g. Limitations to normal shoulder mechanics, suit fit, donning/doffing, body position, pre-existing injury, tool weight and configuration, age, in-suit activity, training density, etc.
Conclusions

2. Despite the injury prevention measures taken from the 2003 Shoulder Tiger Team recommendations, shoulder injuries and subsequent shoulder surgeries remain relatively unchanged
   – 6/12 (50%) of astronauts who attributed their injury leading to surgery to training in the EMU occurred after 2004.
Recommendations

1. Crewmembers with pre-existing or current shoulder injuries or certain anthropometric body types should conduct NBL EVA training in the pivoted HUT.

2. Individuals that have clinical symptoms consistent with shoulder injury associated with NBL EVA training may have alterations to training frequency at the discretion of the evaluating flight surgeon.

3. Develop a training tracking method to electronically document astronaut NBL EMU runs, type of HUT, time in suit, occurrence of injury, whether ice was applied, etc.

4. Team up with shoulder specialists, EVA suit designers, astronauts and flight surgeons to study how proper shoulder biomechanics can be incorporated into existing design configurations, i.e. HUT design

### Current EVA Shoulder Injury Prevention Program

**Pivoted vs. Planar Hard Upper Torso (HUT) for training**
- Identify individuals who are predisposed to shoulder injuries based on prior history of injury, anthropometrics, etc.

**Icing following NBL runs**

**Anti-inflammatory modalities**

**Injury reporting**

**EVA Training Fitness Program**
- Astronaut Strength, Conditioning and Rehabilitation (ASCR) specialists

EVA Fitness Program

- A well rounded exercise plan allows the crew to attain greater overall strength through functional movement patterns
- Prescribe multiple joint/multiple muscle exercise movements
EVA Fitness Program

- Triple Extension & Lower Extremity Based Exercises – Squats, Deadlifts, RDL’s, Hamstring Curls, Kettlebell Swings, etc.
- Pushing Exercises – Bench Press, Shoulder Press, Push-Ups, etc.
- Pulling Exercise – Cable Row, Lat Pulldown, Pull-Ups, etc.
- Accessory Exercises – Shoulder Rotator Cuff Maintenance Program, Wrist/Forearm Exercises
Future Shoulder Injury Prevention Strategies

- EVA Shoulder Fitness Evaluation, i.e. return to duty criteria
- Modify training time/density
- Optimize Pv HUT suit availability
- Identify individuals who have trained in PI HUT without injuries for anthropometric characteristics that may be “protective”
