Introduction

• Composite Vessels are now used to store a variety of fluids or gases including cryogenic fluids under pressure

• Sudden failure of these vessels under certain conditions can lead to a potentially catastrophic vapor expansion if thermal control is not maintained prior to failure

• This can lead to a “Boiling Liquid Expanding Vapor Explosion” or BLEVE
Scope

• BLEVEs
  – Definition
  – “Superheat Energy” and “Superheat Limit”
  – Thermodynamics of BLEVEs
  – Work Available for Blast
    • Reversible Adiabatic
    • Irreversible Isentropic
  – Step-by-step methodology for estimation

• Cryogenic BLEVES
  – Nitrogen Example (Comparison of Blast Potentials)
    • Hydrostatic
    • Pneumatic
    • BLEVE
  – Other Cryogens, Current Work, and Safety
BLEVE

• Boiling Liquid Expanding Vapor Explosion (BLEVE)
  – Any heated fluid under sufficient pressure that is suddenly exposed to lower pressures (ex. ambient) can ‘flash’ to vapor if the fluid temperature is above a certain value known as the 'superheat limit' temperature (Tsl)
  – The mechanism at or above Tsl is a homogeneous nucleation process throughout the entire liquid mass and vaporization proceeds in the millisecond timeframe. This process is similar to rapid combustion in solids that convert solids to gas in the sub-millisecond domain (i.e. explosives).
  – The process creates a co-volume of liquid and a gas near the density of the original liquid acting like a highly pressurized gas volume within the vessel at a pressure typically well in excess of the original design burst pressure.
  – The end result is a blast that is very similar to a non-ideal gas pneumatic burst event and can create significant overpressures posing a risk to life and property.

Typically the Tsl for a wide range of compounds has been found to be:
Tsl ~ 0.89Tc to 0.90Tc
Tc = Critical Temperature of Fluid
Properties of Interest

- **State Variables**
  - $T =$ Temperature (K)
  - $P =$ Pressure (N/m$^2$)
  - $M =$ Mass (kg)
  - $U$, $u =$ Internal energy (kJ), Specific internal energy (kJ/kg)
  - $H$, $h =$ Enthalpy (kJ), Specific enthalpy (kJ/kg)
  - $V$, $v =$ volume (m$^3$). Specific volume (m$^3$/kg)
  - $S$, $s =$ entropy (kJ/K), specific entropy (kJ/kg-K)

- **States Subscripts**
  - Subscript 1 refers to the initial state
  - Subscript 2 refers to the expanded state (ambient)
  - Subscript g refers to state of saturated vapor at ambient conditions (state 2)
  - Subscript f refers to state of saturated liquid at ambient pressure (state 2)
Thermodynamics

• State calculations can be used to estimate the available energy (work) available to generate a blast wave.

• Two bounding values bracket the range of available work:
  – Maximum: Reversible Adiabatic Expansion (isentropic work) = \( W_i = U_1 - U_2 \)
  – Minimum: Irreversible Expansion work against atmospheric pressure \( (W_0 = P_0 \Delta V) \)

• Typically the maximum isentropic work value is used to bound the ‘worse’ case scenario for hazard assessment \( (W_i = \Delta U) \)

• The liquid’s initial internal energy, \( U_1 \), can be found for the initial state using tables or graphs. Since most tables or graphs only supply \( h, \nu \), and \( s \) the value of \( U_1 \) can be found from \( u = h - p\nu \) and the system mass
Step-by-Step Methodology

• First determine the initial state
  – Ideally the exact temperature of the fluid is desirable
  – Alternatively the pressure just prior to BLEVE can be used to determine the maximum temperature of the fluid by assuming saturated conditions

Example: Liquid Nitrogen
– Find Initial state
– Determine if at or above $T_{sl}$
– Solve for initial and final states
Nitrogen Curve

126.1 K, 3.4 mPa, 493.1 psia

Tsl = 112.3 K, 1.825 mPa, 264.7 psia

77.347 K, 0.101325 Mpa, 14.7 psia, 1 atm
Primary Method

Reversible Adiabatic Expansion (Isentropic)
(Isentropic Work, ∆u) (Subscript 1 indicates initial state)

• Find $u_1$ (find $h_1$ and $v_1$ at $P_1$ and $T_1$)
  Where
  \[ u_1 = h_1 - p_1 v_1 \]  
  (eq. 1)

• Find $u_2$ based on:
  \[ u_2 = (1-X)h_f + Xh_g - (1-X)p_2 v_f - Xp_2 v_g \]  
  (eq. 2)
  where
  \[ X = \text{Vapor Ratio} = \frac{(s_1-s_f)}{(s_g-s_f)} \]  
  (eq. 3)
  – Subscript 1 refers to the initial state
  – Subscript 2 refers to the expanded state (ambient)
  – Subscript $g$ refers to state of saturated vapor at ambient conditions (state 2)
  – Subscript $f$ refers to state of saturated liquid at ambient pressure (state 2)
Isentropic Work

Calculated Values are readily available for various compounds

Comparison of various fluids near $T_{sl}$

Comparison of relative isentropic work ($W_i$) potential for various fluids near $T_{sl}$

Blast Characterization

**Basic Method**

1. collect data
2. calculate energy
3. calculated R of target
4. check R
   - R < 2
   - R > 2
5. determine \( P_s \)
6. determine \( T \)
7. adjust \( P_s \) and \( T \)
8. calc. \( p_s \) and \( T \)
9. check \( p_s \)
10. end

**BLEVE**

1. collect data
2. check the fluid
3. determine \( u_1 \)
4. determine \( u_2 \)
5. calculate specific work
6. calculate energy
7. calculate R
8. continue with step 5 of basic method

*Figure 6.20. Basic method.*

*Guidelines for Evaluating the Characteristics of Vapor Cloud Explosions, Flash Fires, and BLEVES, Center for Chemical Process and Safety, American Institute of Chemical Engineers, 1994*
Comparison of Blast Potential (Nitrogen)

- Example: 1 liter (0.001 m^3) of Nitrogen, P_1 = 500 psi (3.45 MPa)

- Stored Energy Comparison
  - Hydrostatic: The approximate stored energy in pressurized liquids is relatively small, (based on a bulk modulus of liquid nitrogen of ~13 Gpa) 1 liter of nitrogen at 500 psi stores
    - ~0.5 J
  - Pneumatic: Nitrogen gas (assumed ideal) at 500 psi and 1 liter can store
    - ~5.5 kJ
  - BLEVE: 1 liter Superheated Liquid Nitrogen at 500 psi (T=126 K) can store up to
    - ~30 kJ
Equivalent Pneumatic System

- The previous calculations showed the ‘work’ available to a BLEVE can be several times that of relatively low pressure (500 psi) gaseous pressure vessel or hydrostatic case
  - BLEVE vs. Pneumatic up to ~6 times greater (in this case)
  - BLEVE vs. Hydrostatic up to ~60,000 times greater (in this case)
- To ‘match’ pneumatic and BLEVE potentials a pneumatically charged nitrogen vessel would be at ~2,250 psi
- Finally it should be noted that nitrogen BLEVEs (or pneumatic releases) generate a local asphyxiation hazard
Other Cryogens

- Liquid Oxygen (LOX) is very similar to liquid nitrogen (LN2) in its BLEVE behavior but has the added hazard of an oxidizer and promoted combustion risks.
- Liquid Hydrogen (LH2)
  - Examination of Characteristics
    - Boiling Point (1 atm) = 20.37 K
    - Critical Point = 32.97 K
    - Tsl (estimate Redlich-Kwong equation of state) = 29.51 K
  - The final result is LH2 BLEVEs have an estimated blast potential less than LN2 (based on mass) but can still be catastrophic and have an additional vapor cloud explosion hazard in air (combustion, deflagration, or deflagration to detonation).

- Current WSTF efforts include:
  - Verifying BLEVE threshold (Tsl) value for Nitrous Oxide (N2O)
  - Determining Blast Potential of Nitrous Oxide BLEVEs
Other Hazards

• Additional Safety Notes
  – Cryogenic systems can condense ‘Air’ and form a liquid consisting of ~50% liquid oxygen and ~50% liquid nitrogen as it drips off the cold surfaces
  – Liquid oxygen when in contact with hydrocarbons or products containing hydrocarbons (ex. oil, grease, asphalt, leather goods, etc.) can form impact or shock sensitive explosive compounds rivaling the strength of similar solid high explosives
