A transponder that may be used as an RFID tag includes a passive circuit to eliminate the need for an “always on” active RF receiving element to anticipate a wake-up signal for the balance of the transponder electronics. This solution allows the entire active transponder to have all circuit elements in a sleep (standby) state, thus drastically extending battery life or other charge storage device life. Also, a wake-up solution that reduces total energy consumption of an active transponder system by allowing all non-addressed transponders to remain in a sleep (standby) state, thereby reducing total system or collection energy. Also, the transponder and wake-up solution are employed in an asset tracking system.

FIG. 4
FIG. 10

- Tag Transceiver
- Processing Unit
- Wireless Network Transceiver
- Power Interface
- To AC Source
This application is a division of U.S. patent application Ser. No. 12/963,773 entitled “Methods and Apparatus for Switching a Transponder to an Active State, and Asset Management Systems Employing Same” filed Dec. 9, 2010, now U.S. Pat. No. 8,022,826, which is a divisional of U.S. patent application Ser. No. 11/678,296 entitled “Methods and Apparatus for Switching a Transponder to an Active State, and Asset Management Systems Employing Same” filed Feb. 23, 2007, now U.S. Pat. No. 7,876,225, which claims the benefit of U.S. Provisional Application No. 60/776,046, entitled “Methods and Apparatus for Switching a Transponder to an Active State, and Asset Management Systems Employing Same,” which was filed on Feb. 23, 2006, the disclosure of which is incorporated herein by reference.

GOVERNMENT CONTRACT

This work was supported in part by a grant from NASA under Contract No. NNN040AZ90C. The United States government may have certain rights in the invention described herein.

FIELD OF THE INVENTION

The present invention relates to transponders, such as RFID tags, and in particular to methods and apparatus for switching a transponder to an active state and asset management system that employ such transponders.

BACKGROUND OF THE INVENTION

The use of radio frequency identification (RFID) systems is expanding rapidly in a wide range of application areas. RFID systems consist of a number of radio frequency tags or transponders (RFID tags) and one or more radio frequency readers or interrogators (RFID readers). The RFID tags include one or more integrated circuit (IC) chips, such as a complementary metal oxide semiconductor (CMOS) chip, and an antenna connected thereto for allowing the RFID tag to communicate with an RFID reader over an air interface by way of RF signals. In a typical RFID system, one or more RFID readers query the RFID tags for information stored on them, which can be, for example, identification numbers, user written data, or sensed data. RFID systems have thus been applied in many application areas to track, monitor, and manage items as they move between physical locations.

RFID tags can generally be categorized as either passive tags or active tags. Passive RFID tags do not have an internal power supply. Instead, the relatively small electrical current induced in the antenna of a passive RFID tag by the incoming RF signal sent from the RFID reader provides enough power for the IC chip or chips in the tag to power up and transmit a response. Most passive RFID tags generate signals by backscattering the carrier signal sent from the RFID reader. Thus, the antenna of a passive RFID tag has to be designed to both collect power from the incoming RF signal and transmit (or reflect, e.g., backscatter) the outbound backscatter signal. Due to power limitations, the ability to provide devices such as sensors or microprocessors on passive RFID tags is limited. Passive RFID tags do, however, have the advantage of a near unlimited lifetime as they obtain their power from the RF signal sent from the RFID reader.

Active RFID tags, on the other hand, have their own internal power source, such as, without limitation, a battery, a fuel cell or what is commonly known as a super capacitor. The internal power source is used to power the IC chip or chips and discrete circuit elements, which typically include an RF receiver, an RF transmitter, and some type of controller, such as a microcontroller or other processor, and any other electronics provided on the active RFID tag. As a result, active RFID tags can include relatively high power devices such as sensors, microprocessors, receivers and transmitters. Also, because of the on-board power, active RFID tags typically have longer ranges and larger memories than passive RFID tags. The internal power source, however, also means that active RFID tags typically have a lifetime that is limited by the lifetime of the power source. Thus, periodic maintenance is required.

As noted above, multiple active RFID tags may be used to track, monitor, and manage multiple items/assets as they move between physical locations. In such an application, each active RFID tag is affixed to an item/asset that is located in a particular location or environment, such as a building. A building shall refer to any structure including, without limitation, a warehouse, a hospital, an office building, or even a vehicle. In current RFID systems, the active RFID tags, when deployed in such a manner, are done so in a state where (i) an RF receiver of the tag is in an active state for receiving RF signals, and (ii) the controller is in a low power inactive (sleep) state to preserve power. When one or more of the active RFID tags are to be queried, the RFID reader sends out a wake-up signal that is received by the RF receiver of each tag. Tags may also be on continuously not requiring a wake-up signal. Upon receipt of the signal, the RF receiver in each tag will then send a signal to the controller of the tag that causes it to move from the inactive state to an active (wake-up) state. For example, in RFID systems implemented according to the ISO 18000 Part 7 standard, when one or more tags are to be queried, the reader will send out a 30 KHz tone lasting for a period of approximately 2.5 seconds. Upon receipt of the tone, the RF receiver in each tag will wake-up the controller in the tag. The RFID reader then sends out signals intended for particular ones of the tags. Those particular tags for which the signals are intended will then perform the requested action, and the remaining tags (i.e., those tags not currently of interest to the reader) will move back to a sleep state.

The multiple active RFID tag arrangement just described presents at least two power management problems. First, each active RFID tag that is deployed is required to have at least one component, i.e., an RF receiver, in an active, relatively high power consuming state and times so that it can listen for the wake-up signal. Second, when the RFID reader needs to query one or more particular tags, all of the tags that are deployed are woken up (for example, according to the ISO 18000, Part 7 standard), i.e., their controllers are caused to move to an active, relatively high power consuming state. Only when a particular tag determines that the query in question is not intended for it will it then move back to the sleep state. As will be appreciated, these problems result in unnecessary use of power from the power source (e.g., battery) of each tag, and therefore decreases the lifetime of each tag.

SUMMARY OF THE INVENTION

The present invention overcomes at least two problems associated with (1) current active RFID tags, and (2) current
active RFID tag wake-up protocols. The first problem is that in current RFID tags, an active RF receiving element must always be awake to anticipate a wake-up signal for the balance of the tag electronics. The present invention uses a passive circuit to eliminate the need for an “always on” active RF receiving element to anticipate a wake-up signal for the balance of the tag electronics. This solution allows the entire active RFID tag to have all circuit elements in a sleep (standby) state, thus drastically extending battery life or other charge storage device life and thus essentially eliminating shelf maintenance on the active RFID tag. The second problem is that in current active RFID tag systems, the electronics of all of the RFID tags in a system are awakened in response to wake-up signals even if the signal is not intended for a particular tag or tags. The present solution provides a major energy saving circuit that eliminates the need to wake up all of the RFID tags in response to each wake-up signal. This circuit thus reduces total energy consumption of an active RFID tag (or sensor) system or collection of devices by allowing all non-addressed tags (sensors) to remain in a sleep (standby) state, thereby reducing total system or collection energy. This second circuit can be used in conjunction with the first passive circuit mentioned above or in conjunction with any existing active RFID tag (sensor) systems. Thus, the elements of the present invention capitalize on the benefits of an active RFID tag while eliminating the problems discussed above, thus moving active RFID tags closer to a passive tag operation.

In one embodiment, the present invention relates to a transponder apparatus, such as, without limitation, an RFID tag, that includes an electronic device, such as a processing unit (e.g., microprocessor or microcontroller), that is capable of being in an inactive, sleep state and an active state, a power source, such as a battery, in electronic communication with the electronic device for providing power to the electronic device, and a switch having an antenna for receiving an at least one RE signal. The switch converts the at least one RF signal into at least one DC signal. The at least one active state, thereby reducing total system or collection energy. This second circuit can be used in conjunction with the first passive circuit mentioned above or in conjunction with any existing active RFID tag (sensor) systems. Thus, the elements of the present invention capitalize on the benefits of an active RFID tag while eliminating the problems discussed above, thus moving active RFID tags closer to a passive tag operation.

In another embodiment, the present invention relates to a method of moving an electronic device, such as a processing unit, included in a transponder apparatus from an inactive, sleep state to an active state, wherein the electronic device consumes power from a power source of the transponder apparatus in the active state. The method includes receiving at least one RF signal and converting the at least one RF signal into at least one DC signal without consuming power from the power source or another power source within or connected to the transponder apparatus. The method further includes providing a wake-up signal to the electronic device in response to receipt of the at least one RF signal that causes the electronic device to move from the inactive, sleep state to the active state. The wake-up signal of the method may, in one particular embodiment, be the at least one DC signal. Alternatively, the method may include determining whether the at least one RF signal or the at least one RF signal has a predetermined format, wherein the providing step comprises providing the wake-up signal (which is separate from the at least one DC signal) to the electronic device to cause the electronic device to move from the inactive, sleep state to the active state. Alternatively, the wake-up signal may be provided to the electronic device only if the at least one RF signal and the at least one additional DC signals are received in a particular sequence.

In another embodiment, the present invention relates to a method of moving an electronic device, such as a processing unit, included in a transponder apparatus from an inactive, sleep state to an active state, wherein the electronic device consumes power from a power source of the transponder apparatus in the active state. The method includes receiving at least one RF signal and converting the at least one RF signal into at least one DC signal without consuming power from the power source or another power source within or connected to the transponder apparatus. The method further includes providing a wake-up signal to the electronic device in response to receipt of the at least one RF signal that causes the electronic device to move from the inactive, sleep state to the active state. The wake-up signal of the method may, in one particular embodiment, be the at least one DC signal. Alternatively, the method may include determining whether the at least one RF signal or the at least one RF signal has a predetermined format, wherein the providing step comprises providing the wake-up signal (which is separate from the at least one DC signal) to the electronic device to cause the electronic device to move from the inactive, sleep state to the active state. Alternatively, the wake-up signal may be provided to the electronic device only if the at least one RF signal and the at least one additional DC signals are received in a particular sequence.

Another aspect of the present invention relates to a system for tracking a plurality of assets that includes a central computer system that maintains a plurality of records relating to the assets, and a plurality of transponders, wherein each of the transponders is associated with a respective one of the assets and stores an identifier identifying the particular asset with which it is associated. Each of the transponders includes an electronic device capable of being in an inactive, sleep state and an active state, a power source in electronic communication with the electronic device for providing power to the
A system for tracking a plurality of assets is described. Each asset may be associated with one or more interface devices that are adapted to communicate with the network. The system includes a central computer system that is in electronic communication with the network, and a plurality of interface devices. Each of the interface devices is adapted to communicate with at least one of the interface devices. In addition, each of the interface devices may be associated with a particular location within an environment such as a building (e.g., a hospital), and each of the interface devices may be associated with a particular location within the environment. Each of the interface devices is adapted to receive a plurality of second response signals, wherein each of the second response signals corresponds to a respective one of the assets and stores an identifier identifying the particular asset with which the transponder is associated. Each of the interface devices may be associated with a respective one of the assets and stores an identifier identifying the particular asset with which it is associated. Each of the transponders is adapted to receive from one of the interface devices at least one RF signal that is generated at the direction of the central computer system and in response thereto to generate and transmit a response signal including the identifier identifying the particular asset with which the transponder is associated. Each of the interface devices is adapted to receive from one of the interface devices at least one RF signal that is transmitted by each of a particular one or more of the transponders, and (ii) generate and transmit to the network at least one second response signal that includes each identifier that was included in each response signal received by the interface device. Each at least one second response signal is transmitted to the central computer system through the network. The central computer system uses the at least one second response signal received from one or more of the interface devices to update one or more of the records.

The at least one second response signal in each case may be a plurality of second response signals, wherein each of the second response signals corresponds to a respective one of the response signals that was received by the interface device and includes the identifier that was included in the corresponding one of the response signals. The central computer system may further be adapted to cause the generation of the at least one RF signal particular to one or more of the transponders in a sequential fashion, wherein corresponding response signals and second response signals are generated and transmitted in a corresponding sequential fashion. Location information associated with each interface device may be used to update the location of each of the assets as described above.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings illustrate presently preferred embodiments of the invention, and together with the general description given above and the detailed description given below, serve to explain the principles of the invention. As shown throughout the drawings, like reference numerals designate like or corresponding parts. FIG. 1 is a block diagram of an active RF transponder according to one embodiment of the present invention.
FIG. 2 is a schematic diagram of a burst switch according to an aspect of the present invention;

FIG. 3 is a block diagram of an RF transponder according to an alternative embodiment of the present invention;

FIG. 4 is a schematic illustration of a code that may be required to awaken the transponder shown in FIG. 3;

FIG. 5 is a block diagram of an RF transponder according to a further alternative embodiment of the present invention;

FIG. 6 is a block diagram of an alternative RF transponder that is similar to the RF transponder shown in FIG. 1 but that further includes an RF receiver;

FIG. 7 is a block diagram of an alternative RF transponder that is similar to the RF transponder shown in FIG. 3 but that further includes an RF receiver;

FIG. 8 is a block diagram of an RFID system according to an aspect of the present invention;

FIG. 9 is a block diagram of an asset management system according to a further aspect of the present invention; and

FIG. 10 is a block diagram of an interface device forming a part of the asset management system shown in FIG. 9.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

FIG. 2 is a schematic diagram of an RF transponder 5 according to one embodiment of the present invention. The RF transponder 5 includes a burst switch 10, which is described in more detail in connection with FIG. 2. The burst switch 10 is in electronic communication with a processing unit 15, which may be, without limitation, a microprocessor, a microcontroller, or some other type of processor device. The processing unit 15 may further include another type of electronic device, such as a CMOS device or any other electronic circuit element provided on, for example, a semiconductor substrate or printed circuit board (PCB), which performs a particular function or functions. The processing unit 15 is capable of being placed into an inactive, sleep state where the current drawn by it is at a minimum. In addition, the processing unit 15 may be woken up, i.e., moved from the inactive, sleep state to an active state, upon receipt of an external input signal. An RF transmitter 20 is in electronic communication with the processing unit 15. The RF transmitter 20 may be a separate transmitter component, or may be part of a transceiver component that is capable of both transmitting and receiving RF signals. The RF transmitter 20 is, in response to commands received from the processing unit 15, able to transmit RF signals through an antenna 25 connected thereto. Like the processing unit 15, the RF transmitter 20 is capable of being placed into an inactive, sleep state where the current drawn by it is at a minimum, and can be woken up by receipt of an external input signal provided by the processing unit 15. The RF transmitter 5 also includes a battery 30 which provides the power required for the operation of the processing unit 15 and the transmitter 20. The battery 30 may alternatively be replaced by another power source, such as, without limitation, a fuel cell or a super capacitor.

FIG. 2 is a schematic diagram of the burst switch 10. The burst switch 10 includes an antenna 35, which, in the embodiment shown in FIG. 2, is a square spiral antenna. The antenna 35 is electrically connected to a matching network 40, which in turn is electrically connected to a voltage boosting and rectifying circuit preferably in the form of a charge pump 45. Charge pumps are well known in the art. Basically, one stage of a charge pump essentially doubles the effective amplitude of an AC input voltage and stores the resulting increased DC voltage on an output capacitor. The voltage could also be stored using a rechargeable battery. Successive stages of a charge pump, if present, will essentially increase the voltage from the previous stage resulting in an increased output voltage. The matching network 40 matches the input impedance of the charge pump 45 to the impedance of the antenna 35 for optimal performance of the antenna 35 and optimal charge pump 45 output voltage. In one particular embodiment, the matching network 40 is an LC tank circuit formed by, for example, the inherent distributed inductance and inherent distributed capacitance of the conducting elements of the antenna 35. The antenna 35 is tuned to receive RF signals having a particular frequency or range of frequencies. The RF signals that are received by the antenna 35 are provided, in the form of an AC signal, to the charge pump 45 through the matching network 40. The charge pump 45 essentially amplifies and rectifies the received AC voltage signal and outputs the resulting DC signal. These operations are performed without requiring the consumption of power from the battery 30 or any other power source within or connected (physically) to the RF transponder 5.

Referring again to FIG. 1, in operation, the RF transponder 5 is deployed in a state wherein the processing unit 15 and the transmitter 20 are in the inactive, sleep state. As such, the draw on the battery 30 will be at a minimum. When it is desired to “wake-up” the RF transponder 5, an RF signal of an appropriate frequency is transmitted to the RF transponder 5 by, for example, an RFID reader or other suitable device. The RF signal is received by the burst switch 10, and as described above, the RF signal is used to produce a DC signal. The DC signal that is produced is provided to the sleep input (pin) of the processing unit 15, which causes the processing unit 15 to move from the inactive, sleep state to its active state. In the active state, the processing unit 15 is able to perform any action that is required, such as waking up the RF transmitter 20 and causing it to transmit a signal that contains information such as an identifier for the RF transponder 5. When finished (or after some predetermined period of time), the processing unit 15 can return to an inactive, sleep state until subsequently woken up as described herein. As will be appreciated, the burst switch 10 as shown in FIG. 2 is designed to produce a DC signal of an appropriate level for input into the sleep input of the processing unit 15 through appropriate selection of the parameters of the antenna 25, the matching network 40 and/or the charge pump 45.

A shortcoming of the RF transponder 5 shown in FIG. 1 is that spurious RF energy (noise) received by the burst switch 10 could inadvertently cause the processing unit 15 to move to the active state, thereby consuming power when not needed. Also, if a number of similar RF transponders 5 (i.e., similar meaning the antenna 35 of each is tuned to the same frequency or frequency range) are deployed together, an RF signal that is transmitted by a reader will activate all of the RF transponders 5 even if they are not all currently of interest to the reader. In other words, there is no way to selectively activate one or more of them without also activating the remaining ones of them.

FIG. 3 is a block diagram of an RF transponder 50 according to an alternative embodiment of the present invention that addresses the shortcomings of the simple RF transponder 5 shown in FIG. 1. As seen in FIG. 3, the RF transponder 50 is similar to the RF transponder 5 in that it includes a burst switch 10, a processing unit 15, an RF transmitter 20 connected to an antenna 25, and a battery 30. However, the RF transponder 50 further includes a low power filtering circuit 55. Specifically, as shown in FIG. 3, the DC output of the burst switch 10 is provided to the filtering circuit 55, and the output of the filtering circuit 55 is provided to the sleep input of the processing unit 15. The function of the filtering circuit 55 is
twofold. First, the filtering circuit $55$ prevents spurious RF energy (noise) from inadvertently causing the processing unit $15$ to move from an inactive, sleep state to an active state. Second, the filtering circuit $55$ provides a mechanism by which the particular RF transponder $50$ in which the filtering circuit $55$ is included can be selectively woken up, i.e., have its processing unit $15$ selectively moved to an active state. The filtering circuit $55$ performs these functions by causing a wake-up signal to be sent to the sleep input of the processing unit $15$ only if a particular sequence or pattern (i.e., format) of RF signals is received by the burst switch $10$.

In the preferred embodiment, the filtering circuit $55$ is a state machine that will generate a wake-up signal only if a particular pre-set "code" is received from the burst switch $10$, wherein the code is a particular sequence of a certain number of voltage "bursts" (i.e., voltage signals of a certain (although possibly varying) length or duration) from the burst switch $10$ each having a particular length expressed as a multiple of some pre-set unit of time, such as 1 millisecond. FIG. 4 shows an example of a 4 element code that may be required to be output by the burst switch $10$ and received by the filtering circuit $55$ in order for the filtering circuit $55$ to generate a wake-up signal for waking up the processing unit $15$. In the example of FIG. 4, the code that must be received is a 4 burst code consisting of a burst of length 5 (e.g., 5 milliseconds), followed by a burst of length 2 (e.g., 2 milliseconds), followed by a burst of length 4 (e.g., 4 milliseconds), followed by a burst of length 6 (e.g., 6 milliseconds). In effect, the code is $5 2 4 6$. As will be appreciated, the code scheme of FIG. 4 is meant to be exemplary only, and any number of bursts of any possible length and any base length unit of time may be used for a particular code without departing from the scope of the invention.

In operation, the filtering circuit $55$ will count possibly on a dedicated counter the number of separate bursts received and the length of each burst (the length of each burst may be stored in a register or any suitable memory). When the count reaches the pre-set number, e.g., 4, the registers (or memory) are checked for the proper code (i.e., has the proper sequence of burst lengths been received). If the code is determined to be correct, the filtering circuit $55$ will generate a wake-up signal for the processing unit $15$. As will be appreciated, the required code may be generated by an RFID reader by generating a sequence of an appropriate number of RF bursts wherein each RF burst is of a particular time. As described in connection with FIG. 2, each such RF burst will result in a corresponding DC voltage (DC burst) being output by the burst switch $10$ having a length equal to the length of the RF burst. Thus, in order to generate the $5 2 4 6$ code described above, an RF reader must output an RF burst having a length of 5 (e.g., 5 milliseconds), followed by an RF burst having a length of 2 (e.g., 2 milliseconds), followed by an RF burst having a length of 4 (e.g., 4 milliseconds), followed by an RF burst having a length of 6 (e.g., 6 milliseconds).

The filtering circuit $55$ thus solves the noise problem by requiring a particular sequence of RF bursts before the processing unit $15$ is awakened. The filtering circuit $55$ also allows a number of RF transponders $50$ to be deployed and selectively and independently awakened. In particular, each transponder $50$ (or set of transponders $50$ to be grouped and awakened together) that is deployed at a location can be provided with a unique code. In order for an RFID reader to wake up a particular transponder $50$ (or set of grouped transponders $50$), the RFID reader will need to generate the appropriate RF bursts. As an alternative, any particular RF transponder $50$ may be provided with more than one code that would enable it to be awakened, wherein one code may be used to awaken the RF transponder $50$ individually, and another code may be used to awaken it as part of a group of particular transponders $50$.

As seen in FIG. 3, the filtering circuit $55$ is connected to the battery $30$ for power purposes. Preferably, the filtering circuit $55$ is a device or component that may enter a low power sleep state. The filtering device $55$ will remain in a sleep state until a burst is received, at which time it will move to an active state (the burst is the wake-up signal), count the burst, measure its duration, and return to sleep until the next burst is received. As a result, minimal power is consumed by the filtering circuit $55$. As will be appreciated, the filtering circuit $55$ thus may be any low power electronic device that can be turned on for a short period of time, increment a counter, measure a burst length, and then go back to sleep.

FIG. 5 is a block diagram of an RF transponder $60$ according to a further alternative embodiment of the present invention that includes an alternate arrangement for addressing the shortcomings of the simple RF transponder $5$ shown in FIG. 1, i.e., the noise problem and the inability to discriminate among multiple transponders. As seen in FIG. 5, the RF transponder $60$ is similar to the RF transponder $5$ in that it includes a processing unit $15$, an RF transmitter $20$ connected to an antenna $25$, and a battery $30$. However, the RF transponder $60$ includes multiple burst switches $10A, 10B, 10C$, and $10D$ wherein the antenna $35$ of each burst switch $10A$, $10B$, $10C$, $10D$ is tuned to a different frequency or range of frequencies (although only four burst switches $10$ are shown, more or less than four may be employed to suit the particular needs of the application in question without departing from the scope of the present invention). In addition, as represented by passive logic combination $65$, the burst switches $10A$, $10B$, $10C$, $10D$ are topologically interconnected in manner that implements a selected logical combination, such as an AND, an OR, or any other logic operation or combination of operations. It will be appreciated that each burst switch $10A$, $10B$, $10C$, $10D$ will only output a DC signal if it receives an RF signal of the appropriate frequency (each referred to as a "burst switch frequency" for convenience). Thus, the passive logic combination $65$ can be chosen to only provide a wake-up signal to the processing unit $15$ if a particular combination of the burst switch frequencies is received. For example, the passive logic combination $65$ could be implemented as an AND such that all of the burst switch frequencies must be received for a wake-up signal to be sent to the processing unit $15$. Alternatively, the passive logic combination $65$ could be implemented with a series of ANDs and ORs such that any two, or any three of the burst switch frequencies or a particular two or a particular three of the burst switch frequencies must be received for a wake-up signal to be sent to the processing unit $15$.

Thus, because particular burst switch frequencies must be used to wake-up the processing unit $15$, the arrangement shown in FIG. 5 prevents spurious RF energy (noise) from inadvertently causing the processing unit $15$ to move from an inactive state to an active state. In addition, the arrangement shown in FIG. 5 may also be used to provide a mechanism by which the particular RF transponder $60$ in which it is included can be selectively woken up, i.e., have its processing unit $15$ selectively moved to an active state. Specifically, a number of transponders $60$ may be deployed with different burst switch frequencies and/or different passive logic combinations $65$ such that an RFID reader can generate appropriate RF signals to selectively wake-up certain ones of the RF transponders $60$. For example, one RF transponder $60$ could be deployed

US 8,258,957 B2
wherein all of the burst switch frequencies are required to wake it up, another RF transponder could be deployed wherein a particular two of the burst switch frequencies are required to wake it up, another RF transponder could be deployed wherein a particular two of the burst switch frequencies are required to wake it up, another RF transponder could be deployed wherein a particular three of the burst switch frequencies are required to wake it up, and so on.

In an alternative embodiment of the RF transponder, instead of providing the passive logic combination 65, the burst switches 10A, 10B, 10C, and 10D could be combined and biased with respect to one another such that the burst frequencies must be received in a particular pre-set order for a wake-up signal to be sent to the processing unit 15. In such an arrangement, each burst switch 10 following a first one of the burst switches 10 would require the preceding burst switch 10 to be energized before it would be capable of outputting a DC signal. In this sense, the arrangement of burst switches 10A, 10B, 10C, 10D functions like an electronic combinational lock, and as such is able to prevent noise from inadvertently waking up the processing unit 15 and is able to allow the RF transponder 60 in which it is implemented to be selectively woken-up.

FIG. 6 is a block diagram of an alternative RF transponder 5' that is similar to RF transponder 5 shown in FIG. 1 except that it further includes an RF receiver 70 connected to an antenna 75. The RF receiver 70 may be caused to move from an inactive, sleep state to an active state by the burst switch 10 in order allow for further communication with the processing unit 15 via the RF receiver 70. The communications may be according to an established standard, such as the ISO 18000 Part 7 standard. Similarly, FIG. 7 is a block diagram of an alternative RF transponder 50' that is similar to RF transponder 50 shown in FIG. 3 except that it also further includes an RF receiver 70 connected to an antenna 75. The RF receiver 70 in this embodiment may be caused to move from an inactive, sleep state to an active state by the burst switch 10 and filtering circuit 55 in the manner described elsewhere herein in order to allow for further communication with the processing unit 15 of the RF transponder 50' via the RF receiver 70.

Again, the communications may be according to an established standard, such as the ISO 18000 Part 7 standard.

FIG. 8 is a block diagram of an RFID system 80 according to an aspect of the present invention. The RFID system 80 includes a plurality of RF transponders 85 deployed in a particular location, such as within a building. The RF transponders 85 may be, without limitation, any of the RF transponder embodiments described herein, such as RF transponder 5, RF transponder 50, or RF transponder 50. The RF transponders 85 may also be an RF transponder as described in co-pending U.S. provisional application Ser. No. 60/673,715 entitled “Method and Device for Reducing Power Consumption of Active RFID Tags,” owned by the assignee of the present invention, the disclosure of which is incorporated herein by reference, or any other type of known or later developed suitable RF transponder. The RFID system 80 further includes an interrogator unit 90 which is in electronic communication with a host (central) computer system 95. Under the control of the host computer system 95, the interrogator unit 90 generates the RF signals (e.g., bursts) that are required to selectively awaken one or more of the RF transponders 85 in the manners described elsewhere herein. Once awakened, each RF transponder 85 may simply transmit some identifying information to the interrogator unit 90 to confirm its presence at the location, or, in those embodiments that permit (e.g., RF transponders 5' and 50'), each RF transponder 85 may receive further communications from the interrogator unit 90 (for example, according to the ISO 18000 Part 7 standard) and respond accordingly. Thus, due to the power conserving capabilities of the RF transponder 5, the RF transponder 5', the RF transponder 50, the RF transponder 50' and the RF transponder 60 described elsewhere wherein, the RFID system 80 is able to operate with minimal power consumption and therefore an extended lifetime. In order to avoid collisions in one embodiment, the RF interrogation response signals are transmitted one at a time in a sequential manner, such as according to an order determined by the unique identifier of each RFID tag 110. Other collision avoidance mechanisms are also possible.

FIG. 9 is a block diagram of an embodiment of an asset management system 100 according to a further aspect of the present invention. The asset management system 100 enables centralized, remote location tracking of a number of assets 105 within a particular location 115, such as, for example and without limitation, a hospital or another environment. The assets 105 may be any type of physical item, including both movable items and items that are permanently or temporarily fixed in place. For example, in a hospital application, the assets 105 may be various types of medical equipment, such as, without limitation, a crash cart, an EKG machine, a wheel chair, a gurney, an oxygen dispenser, a staff member, or a patient. Each of the assets 105 has an RFID tag 110 physically associated therewith, preferably by physically attaching the RFID tag 110 to the asset 105. Each RFID tag 110 is preferably any of the RF transponder embodiments described herein, such as RF transponder 5, RF transponder 5', RF transponder 50, RF transponder 50' or RF transponder 60.

The asset management system 100 further includes a central asset management computer system 120 that is connected to a main network 125. The asset management computer system 120 may include, without limitation, a PC or another suitable computing device that is provided with one or more software applications for implementing the system described herein. As seen in FIG. 9, a number of wireless access points 130 are in electronic communication, preferably wired communication, with the main network 125 and are dispersed throughout the location 115. Each wireless access point 130 is capable of receiving a signal from the main network 125, and thus to the asset management computer system 120, and wirelessly transmitting that signal within a particular defined area. In addition, each wireless access point 130 is capable of receiving wireless signals from within its particular defined area and transmitting those signals to the main network 125, and thus to the asset management computer system 120. The main network 125 and wireless access points 130 thus form a wireless network for the location 115. In the preferred embodiment, the wireless network for the location 115 is a WiFi network that is implemented according to the IEEE 802.11 family of standards, or another suitable standard.

The asset management system 100 also further includes a number of interface devices 135 that are dispersed throughout the location 115. Each interface device 135 is located within the range of at least one of the wireless access points 130. As described in greater detail below, each interface device 135 is capable of receiving wireless (RF) signals from and transmitting wireless (RF) signals to the associated wireless access point 130 according to the appropriate protocol. In addition, each interface device 135 is capable of transmitting RF signals to the RF tags 110 that are in proximity thereto and receiving RF signals from those RF tags 110. In particular, based upon control signals received from the asset management computer system 120 through the main network 125 and
the appropriate wireless access point 130, each interface device 135 is capable of transmitting one or more RF signals to the burst switch 10 of the associated RF tags 110 (in the manner or manners described elsewhere herein in connection with the embodiments of the RF transponder 5, the RF transponder 5', the RF transponder 50, the RF transponder 50' and the RF transponder 60) for purposes of causing the processing unit 15 of the associated RF tags 110 to move to an active state. In addition, each interface device 135 is capable of receiving response signals from the associated RF tags 110 after they have been awakened. In this respect, the interface devices 135 function like RFID readers or interrogators. For reasons that will be explained hereinafter, each interface device 135 is provided with an identifier that uniquely identifies it. Such identifiers enable the asset management computer system 120 to associate each interface device 135 with a particular location within the location 115, such as a particular room or wing in a building. This may be done in the form of a table stored by the asset management computer system 120. Thus, each interface 135 can be located or found to be non-functional through the asset management system 100 itself.

FIG. 10 is a block diagram of an embodiment of the interface device 135 shown in FIG. 9. The interface device 135 includes a processing unit 140, which may be, without limitation, a microprocessor, a microcontroller, or some other type of processor device. The processing unit 140 is electrically connected to a power interface 145 which provides power thereto. The power interface 145 is adapted to be coupled to an AC source, such as a wall outlet, in order to receive an AC voltage. The power interface 145 converts the AC voltage into a DC signal that is suitable for use by the processing unit 140. A wireless network transceiver 150 is provided in electronic communication with the processing unit 140. The wireless network transceiver 150 is adapted to receive wireless (RF) signals from an transmit wireless (RF) signals to one or more wireless access points 130 according to the appropriate protocol, such as 802.11 protocol, using an appropriate frequency, such as 2.45 GHz. In addition, a tag transceiver 155 is provided in electronic communication with the processing unit 140 for enabling the processing unit 140 to transmit appropriate RF signals to the associated RFID tags 110 and to receive appropriate response signals from associated RFID tags 110. Thus, as will be appreciated, the interface device 135 functions as an interface between the two communications systems, i.e., the wireless network implemented by the wireless access points 130 and the wireless communications links to the RFID tags 110. In an alternative embodiment, a separate (dedicated) transmitter may be provided in each interface device 135 for sending the required signals to the burst switch 10, and the tag transceiver 155 may be used for other communication with the RFID tags 110.

In one particular embodiment of the asset management system 100, each of the RFID tags 110 is an RF transponder 5 (or, alternatively, an RF transponder 5'). The burst switch 10 of each of the RF transponders 5 has an antenna 35 that is tuned to a particular frequency or frequency range, such as 433 MHz. In this embodiment, the asset management computer system 120 stores one or more files, such as, without limitation, one or more files in a database, that include for each asset 105 an identification of the asset type (e.g., crash cart, EKG machine, etc.) and a unique identifier for the asset 105. The unique identifier may be, without limitation, a serial number. The RFID tag 110 (i.e., transponder 5) associated with each asset 105 stores the unique identifier for the asset 105. The unique identifier may be stored in a memory of the RFID tag 110 that is part of the processing unit 15 thereof or that is separate from but in electronic communication with the processing unit 15 thereof. When deployed, the processing unit 15 of each RFID tag 110 is in a sleep state, and will remain in that state until awakened as described below.

In operation, this particular embodiment of the asset management system 100 is adapted to track and maintain an inventory of each asset 105 including the particular location of each asset 105 within the location 115. To do so, the asset management computer system 120 periodically or on demand generates an asset interrogation signal. The asset interrogation signal is sent to the main network 125 and then to each wireless access point 130. Each wireless access point 130 then wirelessly transmits the asset interrogation signal according to the appropriate protocol, such as an 802.11 protocol. The wirelessly transmitted asset interrogation signal is received by each interface device 135 that is within the range of each wireless access point 130. In response to receipt of the asset interrogation signal, each interface device 135 generates a second RF interrogation signal having a frequency that will be picked up by the antenna 35 of the burst switch 10 of each RFID tag 110. As described elsewhere herein, when the burst switch 10 of each RFID tag 110 receives the second RF interrogation signal, a DC signal is generated that causes the processing unit 15 of each RFID tag 110 to move to an active state. Each such processing unit 15 is adapted to then cause an RF interrogation response signal of an appropriate frequency (e.g., 433 MHz) to be generated by the associated transmitter 20 in the RFID tag 110. Each RF interrogation response signal includes the unique identifier stored by the RFID tag 110 that generated the RF interrogation response signal. In order to avoid collisions, the RF interrogation response signals are, in one embodiment, transmitted one at a time in a sequential manner, such as according to an order determined by the unique identifier of each RFID tag 110. Other collision avoidance mechanisms are also possible.

The RF interrogation response signals are then received by the respective interface devices 135 (i.e., the interface device 135 that is in proximity to the RFID tag 110 that generated the RF interrogation response signal). Each interface device 135 compiles a list of RF interrogation response signals that it has received, and transmits a second interrogation response signal for the corresponding particular location 115 (FIG. 9) according to the chosen protocol of the wireless network that is implemented. The second interrogation response signal generated and transmitted by each interface device 135 will include the unique identifier of the interface device 135 and the list of RF interrogation response signals compiled by the interface device 135. The second interrogation response signals are then received by the associated wireless access points 130 and transmitted to the asset management computer system 120 through the main network 125.

Upon receipt of the second interrogation response signals, the asset management computer system 120 is able to update the location of each asset 105 in its records. In particular, each second interrogation response signal that is received will include a list of unique identifiers that, as described above, uniquely identify each asset 105. Each second interrogation response signal will also include the identifier of the interface device 135 that sent it, thus identifying the location of that interface device 135. As a result, the asset management computer system 120 can use this information to associate a particular location within the location 115 with each asset 105.

As described elsewhere herein, one of the shortcomings of the RF transponders 5 and 5' is that they could be inadvertently awakened by spurious RF noise. This could present a
be used to awaken each of the RFID tags 110 in the group. For ing an identifier identifying a particular asset with which 

rogated by the asset management computer system 120 in the 

be considered as limited by the foregoing description but is 

particular embodiment, each of the RFID tags 110 is an RE 

transponder when deployed, i.e., there is no way to selectively 

switch frequencies. This embodiment is similar to the 

management system

problem for the embodiment of the asset management system 

just described as the RFID tags 110, being RF transponders 5 or 5* in that embodiment, could be caused to inadvertently send RF interrogation response signals in response to noise. This problem is addressed in an alternative embodiment of the asset management system 100 in which each of the RFID tags 110 is an RF transponder 50 (or, alternatively, an RF transponder 50*) that will be awakened by the same burst code, e.g., 5 2 4 6. In this particular embodiment, operation of the asset management system 100 is similar to that described above. However, in this embodiment, the second RF interrogation signal that is generated by each interface device 135 upon receipt of the asset interrogation signal from a wireless access point 130 will be an RF signal consisting of the appropriate burst bursts sufficient to cause the burst switch 10 of each RFID tag 110 to create the required burst code for the filtering circuit 55 of the RFID tag 110. As described elsewhere herein, that code, when received by the filtering circuit 55, will cause a wake-up signal to be generated for the associated processing unit 15, which, in response, will wake-up and generate the appropriate RF interrogation response signal. Thus, in this embodiment, the adverse affects of noise are minimized.

A further shortcoming of the RF transponders 5 and 5* is that there is no mechanism for discriminating among a number of them when deployed, i.e., there is no way to selectively cause only certain ones of them to respond. As result, the embodiment of the asset management system 100 that utilizes the RF transponder 5 or 5* will be required to interrogate all of the RFID tags 110 each time an inventory update is desired, as opposed to only interrogating selected RFID tags 110 and thus selected assets 105. As will be appreciated, while this will still gather the necessary asset location information, it will cause battery power for certain of the RFID tags 110 to be unnecessarily consumed.

Thus, according to a further aspect of the present invention, a further alternative embodiment of the asset management system 100 provided in which selected ones and/or selected groups of the RFID tags 110 may be interrogated. In this particular embodiment, each of the RFID tags 110 is an RF transponder 50 (or, alternatively, an RF transponder 50*) that may be awakened by a burst code that is unique to that RFID tag 110. For example, each individual RFID tag 110 may be assigned a unique 4 element burst code as described elsewhere herein (such as 5 2 4 6) (4 4 element burst code is merely an example, and it should be understood that the burst code may have more or less than 4 elements). As a result, each of those RFID tags 110 may be selectively, individually interrogated by the asset management computer system 120 in the manner described elsewhere herein using the appropriate burst code in order to determine the current location thereof.

In addition, one or more of the RFID tags 110 may also be adapted to be awakened by a particular burst code that is common to a selected group of RFID tags 110. In other words, certain groups of RFID tags 110 (and thus certain groups of assets 105) may also be assigned a second burst code that may be used to awaken each of the RFID tags 110 in the group. For example, all assets 105 of type one (e.g., crash carts, or assets on floor one of a building) may be assigned the burst code 4 2 4 3, all assets 105 of type two (e.g., EKG machines, or assets on floor two of a building) may be assigned the burst code 3 1 4 2, etc. As a result, the location of all assets 105 in a particular group, such as crash carts, can be readily determined, if desired, by the asset management system 100 using a single burst code.

As will be appreciated, in the embodiment of the asset management system 100 just described, each asset interrogatio-
direction of said central computer system, said switch converting said at least one RF signal into at least one DC signal; wherein said at least one DC signal causes said electronic device to move from said inactive, sleep state to said active state, wherein when said electronic device is in said active state the transponder generates and transmits a response signal including the identifier identifying the particular asset with which the transponder is associated, and wherein said response signal is used to update a particular one of the record maintained by the central computer system relating to the asset identified by the identifier in the response signal; a network, said central computer system being in electronic communication with said network; a plurality of wireless access points, each of said wireless access points being in electronic communication with said network; and a plurality of interface devices, each of said interface devices being adapted to (i) wirelessly communicate with at least one of said wireless access points, (ii) receive the response signal transmitted by a particular one or more of said transponders, and (iii) generate and transmit to the at least one of said wireless access points at least one second response signal that includes each identifier that was included in each response signal received by the interface device; wherein each at least one second response signal is transmitted to said central computer system through said network, and wherein said central computer system uses the at least one second response signal received from one or more of said interface devices to update one or more of said records.

2. The system according to claim 1, wherein the switch in each of the transponders does not require power from the power source of the transponder or another power source within or connected to the transponder.

3. The system according to claim 1, wherein said network and said wireless access points implement a wireless network according to the IEEE 802.11 set of standards.

4. The system according to claim 1, further comprising a wired network in electronic communication with said central computer system, said transponders being adapted to communicate with said central computer system through said wired network.

5. The system according to claim 1, wherein said assets are located within an environment, wherein each of said interface devices is associated with a particular location within said environment, wherein each of said second response signals includes an identification of the interface device from which it was transmitted, and wherein said central computer system uses the identification included in each second response signal to update in said records a location of one or more of said assets.

6. The system according to claim 5, wherein said environment is one or more buildings.

7. The system according to claim 6, wherein said one or more buildings includes a hospital.

8. The system according to claim 1, wherein the power source in each of the transponders is a battery.

9. The system according to claim 1, wherein the electronic device in each of the transponders is a processing unit.

10. The system according to claim 9, wherein each of said transponders includes an RF transmitter in electronic communication with the processing unit of the transponder.

11. The system according to claim 9, wherein each of said transponders includes an RF receiver in electronic communication with the processing unit of the transponder.

12. The system according to claim 1, wherein the antenna in each of the transponders is tuned to a particular frequency or range of frequencies, and wherein the at least one RF signal generated at the direction of said central computer system and received by the antenna in each of the transponders has a frequency that is substantially equal to said particular frequency or is within said range of frequencies.

13. The system according to claim 1, wherein the at least one DC signal of the switch in each of the transponders is provided to the electronic device of the transponder to directly cause the electronic device to move from said inactive, sleep state to said active state.

14. The system according to claim 1, wherein the at least one DC signal of each of said transponders is provided to the electronic device of the transponder to directly cause the electronic device to move from said inactive, sleep state to said active state.

15. The system according to claim 1, wherein each of said transponders is an RFID tag and wherein said at least one RF signals are generated by an RFID reader device.

16. A system for tracking a plurality of assets, comprising: a central computer system, said central computer system maintaining a plurality of records relating to said assets; a plurality of transponders, each of said transponders being associated with a respective one of said assets and storing an identifier identifying a particular asset with which the transponder is associated, wherein each of said transponders comprises: an electronic device, wherein said electronic device moveable between an inactive, sleep state and an active state; a power source in electronic communication with said electronic device, said power source providing power to said electronic device; and a switch having an antenna for receiving at least one RF signal, said at least one RF signal being generated at a direction of said central computer system, said switch converting said at least one RF signal into at least one DC signal; wherein said at least one DC signal causes said electronic device to move from said inactive, sleep state to said active state, wherein when said electronic device is in said active state the transponder generates and transmits a response signal including the identifier identifying the particular asset with which the transponder is associated, and wherein said response signal is used to update a particular one of the record maintained by the central computer system relating to the asset identified by the identifier in the response signal; a network, said central computer system being in electronic communication with said network; and a plurality of interface devices, each of said interface devices being adapted to (i) communicate with said network, (ii) receive the response signal transmitted by a particular one or more of said transponders, and (iii) generate and transmit to said network at least one second response signal that includes at least each identifier that was included in each response signal received by the interface device; wherein each at least one second response signal is transmitted to said central computer system through said network, and wherein said central computer system uses the identification included in each second response signal to update one or more of said records relating to said assets.
the at least one second response signal received from one or more of said interface devices to update one or more of said records.

17. The system according to claim 16, wherein said assets are located within an environment, wherein each of said interface devices is associated with a particular location within said environment, wherein each of said second response signals includes an identification of the interface device from which it was transmitted, and wherein said central computer system uses the identification included in each second response signal to update in said records a location of one or more of said assets.

18. The system according to claim 17, wherein said environment is one or more buildings.

19. The system according to claim 18, wherein one or more buildings includes a hospital.

20. A system for tracking a plurality of assets, comprising: a central computer system, said central computer system maintaining a plurality of records relating to said assets; a plurality of transponders, each of said transponders being associated with a respective one of said assets and storing an identifier identifying a particular asset with which the transponder is associated, wherein each of said transponders comprises:
- an electronic device, wherein said electronic device moveable between an inactive, sleep state and an active state;
- a power source in electronic communication with said electronic device, said power source providing power to said electronic device; and
- a switch having an antenna for receiving at least one RF signal, said at least one RF signal being generated at a direction of said central computer system, said switch converting said at least one RF signal into at least one DC signal;
- wherein said at least one DC signal causes said electronic device to move from said inactive, sleep state to said active state, wherein when said electronic device is in said active state the transponder generates and transmits a response signal including the identifier identifying the particular asset with which the transponder is associated, and wherein said response signal is used to update a particular one of the record maintained by the central computer system relating to the asset identified by the identifier in the response signal, wherein each of the transponders further comprises a filtering circuit in electronic communication with the switch of the transponder, wherein the at least one DC signal from the switch is provided to the filtering circuit, and wherein the filtering circuit provides a wake-up signal to the electronic device of the transponder to cause the electronic device to move from the inactive, sleep state to the active state only if the at least one RF signal generated at the direction of said central computer system and received by the antenna in the transponder has a predetermined format.

21. The system according to claim 20, wherein the predetermined format for each of the transponders comprises a predetermined number of RF bursts, each of said RF bursts having a predetermined duration.

22. A system for tracking a plurality of assets, comprising: a central computer system, said central computer system maintaining a plurality of records relating to said assets; a plurality of transponders, each of said transponders being associated with a respective one of said assets and storing an identifier identifying a particular asset with which the transponder is associated, wherein each of said transponders comprises:
- an electronic device, wherein said electronic device moveable between an inactive, sleep state and an active state;
- a power source in electronic communication with said electronic device, said power source providing power to said electronic device; and
- a switch having an antenna for receiving at least one RF signal, said at least one RF signal being generated at a direction of said central computer system, said switch converting said at least one RF signal into at least one DC signal;
- wherein said at least one DC signal causes said electronic device to move from said inactive, sleep state to said active state, wherein when said electronic device is in said active state the transponder generates and transmits a response signal including the identifier identifying the particular asset with which the transponder is associated, and wherein said response signal is used to update a particular one of the record maintained by the central computer system relating to the asset identified by the identifier in the response signal, wherein each of the transponders further comprises a filtering circuit in electronic communication with the switch of the transponder, wherein the at least one DC signal from the switch is provided to the filtering circuit, and wherein the filtering circuit provides a wake-up signal to the electronic device of the transponder to cause the electronic device to move from the inactive, sleep state to the active state only if the at least one RF signal generated at the direction of said central computer system and received by the antenna in the transponder has a predetermined format.
21. With the switch of the transponder, wherein the at least one DC signal from the switch is provided to the filtering circuit, and wherein the filtering circuit provides a wake-up signal to the electronic device of the transponder to cause the electronic device to move from the inactive, sleep state to the active state only if the at least one DC signal has a predetermined format.

26. The system according to claim 25, wherein the predetermined format for each of the transponders comprises a predetermined number of DC bursts, each of said DC bursts having a predetermined duration.

27. The system according to claim 26, wherein the predetermined format for each of the transponders is different.

28. A system for tracking a plurality of assets, comprising:
- a central computer system, said central computer system maintaining a plurality of records relating to said assets;
- a plurality of transponders, each of said transponders being associated with a respective one of said assets and storing an identifier identifying a particular asset with which the transponder is associated, wherein each of said transponders comprises:
  - an electronic device, wherein said electronic device moveable between an inactive, sleep state and an active state;
  - a power source in electronic communication with said electronic device; and
  - a switch having an antenna for receiving at least one RF signal, said at least one RF signal being generated at a direction of said central computer system, said switch converting said at least one RF signal into at least one DC signal;
wherein said at least one DC signal causes said electronic device to move from said inactive, sleep state to said active state, wherein when said electronic device is in said active state the transponder generates and transmits a response signal including the identifier identifying the particular asset with which the transponder is associated, and wherein said response signal is used to update a particular one of the record maintained by the central computer system relating to the asset identified by the identifier in the response signal, and wherein each of the transponders further comprises one or more additional switches, each of said additional switches of the transponder having an additional antenna for receiving at least one additional RF signal generated at the direction of said central computer system, said additional switch of the transponder converting said at least one additional RF signal into at least one additional DC signal, wherein said at least one additional RF signal received by the antenna of the switch of the transponder and each of said at least one additional RF signals received by the one or more additional switches of the transponder have different frequencies, and wherein the electronic device of the transponder is caused to move from said inactive, sleep state to said active state only if the at least one DC signal and the at least one additional DC signals of the transponder are created in a particular sequence.

30. A system for tracking a plurality of assets comprising:
- a central computer system, said central computer system maintaining a plurality of records relating to said assets;
- a plurality of transponders, each of said transponders being associated with a respective one of said assets and storing an identifier identifying a particular asset with which the transponder is associated, wherein each of said transponders comprises:
  - an electronic device, wherein said electronic device moveable between an inactive, sleep state and an active state;
  - a power source in electronic communication with said electronic device, said power source providing power to said electronic device; and
  - a switch having an antenna for receiving at least one RF signal, said at least one RF signal being generated at a direction of said central computer system, said switch converting said at least one RF signal into at least one DC signal;
wherein said at least one DC signal causes said electronic device to move from said inactive, sleep state to said active state, wherein when said electronic device is in said active state the transponder generates and transmits a response signal including the identifier identifying the particular asset with which the transponder is associated, and wherein said response signal is used to update a particular one of the record maintained by the central computer system relating to the asset identified by the identifier in the response signal.
32. A system for tracking a plurality of assets, comprising:

a central computer system, said central computer system maintaining a plurality of records relating to said assets;
a plurality of transponders, each of said transponders being associated with a respective one of said assets and storing an identifier identifying a particular asset with which the transponder is associated, wherein each of said transponders comprises:
an electronic device, wherein said electronic device is moveable between an inactive state and an active state;
a power source in electronic communication with said electronic device, said power source providing power to said electronic device; and
a switch having an antenna for receiving at least one RF signal, wherein said at least one RF signal is in said active state the transponder generates and transmits a response signal including the identifier identifying the particular asset with which the transponder is associated, and wherein said response signal is used to update a particular one of the record maintained by the central computer system relating to the asset identified by the identifier in the response signal, wherein each of said transponders in order for the at least one RF signal received by the transponder to be converted in at least one DC signal that will cause the electronic device of the transponder to move from the inactive, sleep state to the active state, the at least one RF signal received by the transponder being formatted according to a predetermined number of RF bursts, each of said RF bursts having a predetermined duration.

33. A system for tracking a plurality of assets, comprising:

a central computer system, said central computer system maintaining a plurality of records relating to said assets;
a plurality of transponders, each of said transponders being associated with a respective one of said assets and storing an identifier identifying a particular asset with which the transponder is associated, wherein each of said transponders comprises:
an electronic device, wherein said electronic device is moveable between an inactive state and an active state;
a power source in electronic communication with said electronic device, said power source providing power to said electronic device; and
a switch having an antenna for receiving at least one RF signal, wherein said at least one RF signal is in said active state the transponder generates and transmits a response signal including the identifier identifying the particular asset with which the transponder is associated, and wherein said response signal is used to update a particular one of the record maintained by the central computer system relating to the asset identified by the identifier in the response signal, wherein each of said transponders in order for the at least one RF signal received by the transponder to be converted in at least one DC signal that will cause the electronic device of the transponder to move from the inactive, sleep state to the active state, the at least one RF signal received by the transponder being formatted according to a predetermined number of RF bursts, each of said RF bursts having a predetermined duration.
34. The system according to claim 33, wherein said code associated with each of said groups of transponders represents a predetermined number of RF bursts, each of said RF bursts having a predetermined duration.

35. A system for tracking a plurality of assets, comprising:
   a central computer system, said central computer system maintaining a plurality of records relating to said assets;
   a plurality of transponders each of said transponders being associated with a respective one of said assets and storing an identifier identifying a particular asset with which the transponder is associated, wherein each of said transponders comprises:
   an electronic device, wherein said electronic device moveable between an inactive, sleep state and an active state;
   a power source in electronic communication with said electronic device, said power source providing power to said electronic device; and
   a switch having an antenna for receiving at least one RF signal, said at least one RF signal being generated at a direction of said central computer system, said switch converting said at least one RF signal into at least one DC signal;
   wherein said at least one DC signal causes said electronic device to move from said inactive, sleep state to said active state, wherein when said electronic device is in said active state the transponder generates and transmits a response signal including the identifier identifying the particular asset with which the transponder is associated, and wherein said response signal is used to update a particular one of the record maintained by the central computer system relating to the asset identified by the identifier in the response signal, wherein said transponders are grouped into one or more groups of selected ones of said transponders, and wherein for each of said groups of transponders in order for the at least one RF signal received by each transponder in the group to be converted in at least one DC signal that will cause the electronic device of the transponder in the group to move from the inactive, sleep state to the active state, the at least one RF signal received by the transponder in the group must be have a predetermined format associated with group.

36. The system according to claim 35, wherein said predetermined format associated with each of said groups of transponders comprises a predetermined number of RF bursts, each of said RF bursts having a predetermined duration.
