Changing the Game in Space Exploration

Human Mars Exploration must change from a 3-year epic event to an annual expedition.

Opposition Class Missions
Nuclear Electric Propulsion
Split Mission; ECCV Return
Piloted Vehicle w/ 40 MT Habitat
30-day Surface Stay
Vehicle disposed upon return

Conjunction Class Missions
(900 day total)

Mars Architecture Study 5.0:
Nuclear Thermal Propulsion
Piloted Vehicle w/ 50 MT Habitat
350 MT IMLEO
Vehicle disposed upon return

Development of direct conversion with ion sources paces availability of low-\(\alpha\) in-space power & propulsion.
Direct energy conversion technology is key to attaining low-$\alpha$ in-space propulsion

A generic multi-MW configuration:
Direct energy conversion technology is key to attaining low-$\alpha$ in-space propulsion

*Multi-MW heat sources (e.g., NEP) can enable moderate $\alpha$.***
Direct energy conversion technology is key to attaining low-$\alpha$ in-space propulsion

**Multi-MW ion sources with direct conversion can enable lower $\alpha$.**

The Problem

- Neutronic sources
  - Nuclear Fission *(Thin core)*
  - Nuclear Fusion *(D+$^3$He, p+$^{11}$B)*

Neutron Shielding

Direct Conversion

- *Charged particle deceleration in electric fields*

```
I_{sp} = \sim 10^4 \text{ sec}
```

Thrust
Direct energy conversion technology is key to attaining low-$\alpha$ in-space propulsion. Multi-MW ion sources with TWDEC can enable low $\alpha$:

**The Problem**

Neutron Shielding

Energy Source

Neutronic sources
- Nuclear Fission (Thin core)
- Aneutronic sources
- Nuclear Fusion ($D-^3He, p-^{11}B$)

Energy Conversion

Direct Conversion
- Charged particle deceleration in electric fields (TWDEC)

Electric Propulsion

$\text{i}_{sp} \approx 10^4 \text{ sec}$

Thrust
The Problem

Direct energy conversion technology is key to attaining low-$\alpha$ in-space propulsion

Multi-MW ion sources with TWDEC and direct propulsion conversion can enable lowest $\alpha$.

Neutron Shielding

- Neutronic sources
  - Nuclear Fission
    - Thin core
  - Aneutronic sources
  - Nuclear Fusion
    - $D^3He, p^{11B}$

Energy Source → Energy Conversion → Direct Conversion • TWDEC → PMAD → Electric Propulsion

- Electricity
- Ions
- Ions (wasted)
- Heat

Radiator

Electric Propulsion

- Thrust
- $l_{sp} = \sim 10^4$ sec
- Heat
The Problem

Direct energy conversion technology is key to attaining low-\(\alpha\) in-space propulsion

Direct conversion is the nexus of all the technologies necessary for a truly “game-changing” in-space propulsion and power system.
Options for Low-\(\alpha\) Propulsion and Power Systems for Mars and Beyond
(For 30 MW\(_e\) class)

**NEP 5 year, 1200 K Fission Reactor with K-Rankine conversion, current PMAD, and Plasma EP**
\[ \alpha = 16 \text{ kg/kW}_e \]

1200 K Fission \(\rightarrow\) K-Ra \(\rightarrow\) Q
E Prop \(\rightarrow\) PMAD \(\rightarrow\) Q

Requires Nuclear Testing for Fuel Certification and Flight Qualification

**NEP 2 year, 1500 K Fission Reactor with K-Rankine conversion, advanced PMAD, and Plasma EP**
\[ \alpha = 10 \text{ kg/kW}_e \]

1500 K Fission \(\rightarrow\) K-Ra \(\rightarrow\) Q
E Prop \(\rightarrow\) PMAD \(\rightarrow\) Q

Further High Temperature Fuel Element Certification

**NEP “Massless” Fission or D-T Fusion Reactor at 1500 K with K-Rankine conversion, advanced PMAD, and Plasma EP**
\[ \alpha = 9 \text{ kg/kW}_e \]

“Magic” \(\alpha = 0\) \(\rightarrow\) K-Ra \(\rightarrow\) Q
E Prop \(\rightarrow\) PMAD \(\rightarrow\) Q

Aneutronic Fusion with \(T_{\text{top}} = 1500\) K, K-Rankine Conversion, and Plasma EP
\[ \alpha = 15 \text{ kg/kW}_e \]

\(p^{11}\text{B Fusion} \rightarrow\) K-Ra \(\rightarrow\) Q
E-Prop \(\rightarrow\) PMAD \(\rightarrow\) Q

Aneutronic Fusion with TWDEC and Plasma EP
\[ \alpha = 3 \text{ kg/kW}_e \]

\(p^{11}\text{B Fusion} \rightarrow\) PMAD \(\rightarrow\) Q
E-Prop \(\rightarrow\) DEC-P \(\rightarrow\) Q

Aneutronic Fusion with TWDEC and Direct Conversion Plasma EP
\[ \alpha = 1 \text{ kg/kW}_e \]

\(p^{11}\text{B Fusion} \rightarrow\) DEC-P \(\rightarrow\) T
PMAD \(\rightarrow\) Q

Aneutronic fusion reactors for space applications will require more aggressive $q$ performance than those for civil power generation.
Direct Conversion Options for Ion Energy Output
Literature Survey Results

Charge Collector – TRL 1
• Conceptual design only
• Intended for “Polywell” aneutronic reactor output with MeV energies.
• DC output
  • $\alpha = ?, \eta = ?$
  Bussard, Some Physics Considerations of Magnetic Inertial Electrostatic Confinement, Fusion Technology, 1991

Periodic Focusi
• Preliminary design and computer modeling only
• Intended for scavenging energy from D-T “mirror” confinement end leakage (~150 keV energies)
• DC output
  • $\alpha = ?, \eta = \sim 0.6$
  Barr, Howard, and Moir (LLNL), Computer Simulation of the Periodic Electrostatic Focusing Converter, IEEE Transactions on Plasma Science, 1977

“Venetian Blind” Convertor – TRL 3
• Preliminary design study and subscale testing
• Intended for scavenging energy from D-T “mirror” confinement end leakage (~150 keV energies)
• DC output
  • $\alpha = ?, \eta = \sim 0.6$
  Barr, Moir (LLNL), Test Results On Plasma Direct Converters. Nuclear Technology/Fusion, 1983.

Traveling Wave Direct Energy Converter – TRL 3
• Preliminary design study (1991) and subscale testing (1998 - 2008)
• Originally intended for primary power from of D-3He “pinch confinement” (~15 MeV energies); studied for space applications with IEC fusion.
• RF output
  • $\alpha = \sim 0.14 \text{ kg/kW}_{\text{in}}, \eta = \sim 0.7$
  Momota (NIFS-Japan), Miley (U. of Illinois), et al, Conceptual Design of the D-3He Reactor ARTEMIS, Fusion Technology, 1992
State of the Art: 
The Traveling Wave Direct Energy Convertor (TWDEC)

Conceptual design of half of a conversion system for a D-^3^He reactor with a "venetian blind" DEC for 810 MW of thermal (keV) alpha particles and a TWDEC for 368 MW of 15 MeV protons. 

Schematic of a conversion system for a D-^3^He reactor for a D-^3^He reactor with a CUSPDEC for collection of electrons and thermal (keV) alpha particles and a TWDEC for 15 MeV protons. 

Modulator: Fusion product ions in a beam are “bunched” as they pass through evenly spaced grids of alternating potential.

Decelerator: On each of the grids through which it passes, the ion “bunch” creates an electric potential higher than adjacent grids, which can drive an AC signal. Frequency is set by grid spacing, which decreases as the “bunches” give up energy and slow.

Inefficiencies come from beam thermalization, particle collisions with the grids, and residual, uncollected energy of particles downstream.
TWDEC originally conceived as direct conversion system for “ARTEMIS” D-^3^He, Maxwellian plasma test reactor for utility grid power.

[Momota 1992].

Estimated performance in ARTEMIS application

- Convert 183 MW from 14.7 MeV protons of ρ_{beam} \sim 10^{10} \text{ m}^{-3}; Low ρ_{beam} requires large (R_{beam} = 5 \text{ m}) electrodes
- Predicted η = 0.7; electrode grid collisions rejected as heat
- Estimated α (w/o vacuum structure) = 0.14 kg/kW

Opportunities/issues with η and α for spacecraft applications

a) Decreased electrode collisions can minimize losses to be rejected as heat (e.g., replace grids with hollow electrodes)

b) Increased beam density can improve inductive coupling with electrodes and decrease electrode size (e.g., increase of ρ_{beam} to \sim 10^{14} \text{ m}^{-3} with 3 MeV p-^1^B alpha particles would enable 100 MW carried in R_{beam} of 10 cm)

c) Narrowed relative thermal energy spread can improve inductive coupling with electrodes

d) Limited particle neutralization in ion beam can improve η

e) Adaptation to possible bimodal or broad spectrum alpha particle beam from p-^1^B fusion can improve η
TWDEC Research to date

a) Electrode Collision Losses

Modeling indicates 20% loss in $\eta$ due to ion collisions with electrode grids [Shoyama, 1996]

b) Beam Densification

Hollow electrode experiments with keV beams indicate $\eta$ maintained with $\rho_{\text{beam}} = 10^{12}$ m$^{-3}$ [Kawana, 2008]

c) Thermal Spread Mitigation

Experiments with keV beams indicate beam acceleration in modulator can decrease relative thermal energy spread and increase $\eta$ [Takeno, 2011a, 2010a]

d) Mitigation of Ion Neutralization and Electron Leakage

Experiments with keV beams indicate improvement in $\eta$ due electron deflection in Cusp-type beam preconditioning and with electrode negative bias [Takeno 2010a, 2010b, 2011a; Taniguchi 2010]

e) Harnessing Broad Spectrum or Bimodal Beams

Modeling indicates that dual-beam or “fan” TWDECs can efficiently harness potentially non-mono-energetic ion beams from p-$^{11}$B reactors. [Takeno 2010a, 2010b, 2011a; Stave 2011]
Proposed NASA TWDEC Experiment Facility

Phase 1 NASA test article will enable further model validation of TWDEC $\alpha$ and $\eta$ improvements with keV alpha particles of $\rho_{\text{beam}}$ up to $10^{15} \text{ m}^{-3}$ and with variable electrode biases and geometries.

All major components will be in place by FY12end.

Direct Energy Conversion to Thrust

NIAC Phase I

28 September 2012

Fast ion “bunches” exhausting from a TWDEC may be able to be used to accelerate and heat slow plasma bunches created from inert gas propellant, thus lowering $I_{sp}$ from $10^6$ sec to $10^3$ sec and thereby increasing thrust.

**STEP 1.** Injecting the alpha's with a large angle w.r.t. the axis of a solenoidal magnetic field: the longitudinal speed will be reduced and particles follow a spiral orbit.

The gyro radius for a 2.9 MeV a-particle in a 1 T field is about 0.25 m.

Bunching can provide the non-adiabatic injection required to capture the ions.

**STEP 2.** With a collimated pencil-beam the injected bunch turns into a hollow cylindrical layer with current density $j$.

**STEP 3.** As more particles are collected the current in the layer increases that, in turn, increases the magnetic field.

**STEP 4.** Higher current density produces “magnetic piston effect.”
• Concept actively studied 1957-late 1960’s.

• Studies restarted under DOE “Nuclear Energy Research Initiative” in early 2000’s.
  • Energy conversion by means of high voltage DC electrodes.
  • For terrestrial power: Offers higher efficiency conversion and spent fuel burn-up.

Fission DEC-to-Power
TWDEC Application

• Solenoidal magnetic field $B_0 = 0.5 \, T$:
  - $^{140}\text{Xe}$ fragment gyroradius $= 1.71 \, m$

• Side injection can reduce drift speed and TWDEC frequency

• Bunching can provide the non-adiabatic injection required to capture the ions.
Fusion Fuel Pairs (Product Energy)

- $D + T = n^0 (14.07 \text{ MeV}) + ^4\text{He} (3.52 \text{ MeV})$
- $D + D = n^0 (2.45 \text{ MeV}) + ^3\text{He} (0.82 \text{ MeV}) \text{ (50%)}$
- $D + D = p (3.02 \text{ MeV}) + ^3\text{T} (1.01 \text{ MeV}) \text{ (50%)}$
- $D + ^3\text{He} = p (14.68 \text{ MeV}) + ^4\text{He} (3.67 \text{ MeV})$
- $p + ^{11}\text{B} = 3 ^4\text{He} (8.7 \text{ MeV})$

Fusion reactions can occur in both high temperature, thermalized plasmas and low temperature, monoenergetic colliding beams.
