Effects of Annealing Process on the Formability of Friction Stir Welded Al-Li alloy 2195 Plates

Po-Shou Chen, Carolyn Russell

Abstract

Large rocket cryogenic tank domes have typically been fabricated using Al-Cu based alloys like Al-Cu alloy 2219. The use of aluminum-lithium based alloys for rocket fuel tank domes can reduce weight because aluminum-lithium alloys have lower density and higher strength than Al-Cu alloy 2219. However, Al-Li alloys have rarely been used to fabricate rocket fuel tank domes because of the inherent low formability characteristic that make them susceptible to cracking during the forming operations.

The ability to form metal by stretch forming or spin forming without excessive thinning or necking depends on the strain hardening exponent “n”. The stain hardening exponent is a measure of how rapidly a metal becomes stronger and harder. A high strain hardening exponent is beneficial to a material’s ability to uniformly distribute the imposed strain.

Marshall Space Flight Center has developed a novel annealing process that can achieve a work hardening exponent on the order of 0.27 to 0.29, which is approximately 50% higher than what is typically obtained for Al-Li alloys using the conventional method. The strain hardening exponent of the Al-Li alloy plates or blanks heat treated using the conventional method is typically on the order of 0.17 to 0.19.

The effects of this novel annealing process on the formability of friction stir welded Al-Li alloy blanks are being studied at Marshall Space Flight Center. The formability ratings will be generated using the strain hardening exponent, strain rate sensitivity and forming range. The effects of forming temperature on the formability will also be studied. The objective of this work is to study the deformation behavior of the friction stir welded Al-Li alloy 2195 blank and determine the formability enhancement by the new annealing process.
Effects of Annealing Process on the Formability of Friction Stir Welded Al-Li alloy 2195 Plates

Spun-Formed Dome Development for Ares 1 Upper Stage LH$_2$ Tank

- 2195 dome (5 m) for LH$_2$ tank – can be manufactured by spin forming

- 2195 dome is currently manufactured by gore construction, tedious & complex process
- Spun formed 2195 dome can save weight & costs; being developed by NASA
2195 nominal composition: Al-4%Cu-1.0%Li-0.3%Ag-0.3%Mg-0.1%Zr

- The Al alloy with the highest specific strength – most weight saving potential

### Increasing specific strength for weight saving

Spin Forming being Developed to Replace Current Gore Construction

Traditional Approach – Gore Construction

Plate → Stretch forming → Mandrel → Dome Gore Panel → Dome Gores → Welded Gore Assy. Dome

Developmental Spin forming Approach

Plate → FSW dome blank → Spin forming process → Spun Formed Dome

Benefits:
- Improved safety and mission success
- Reduced part count
- Reduced weld count

Mass Savings:
- Elimination of weld lands
- Higher strength material

Cost Savings:
- Reduced material quantity
- Reduced production labor

Status:
- Production application
  - Any Aluminum alloy domes
  - Up to 5.5 meter diameter

5/25/2011
Development of 5 m Diameter Spun-formed Dome

Aluminum-Lithium Alloys
• High strength / weight ratio
• Good SCC resistance

Friction Stir Welding
• Greater strength & ductility than fusion welding
• Low defect occurrence

Spin Forming
• Single piece near net shape manufacturing
• Lower manufacturing costs
• Improved mass fraction
• Improved system reliability

FSW Spun Formed Dome
5 m dia. Al-Li 2195

Join 2 plates into a big blank
1. Abnormal grain growth (AGG) in the FSW
   - Grain size increase from 10 µm to more than 1 mm (more than 100 x increase)
   - AGG reduces the ductility/toughness to very low level
   - Working to optimize FSW, spin forming, and thermo-mechanical processing parameters for AGG mitigation

2. Micro-cracking in the FSW
   - Microcracks are located in the FSW
   - Microcracks are stress risers and make the dome susceptible to catastrophic failure
   - Developing a favorable post-weld anneal to prevent microcracking in FSW

AGG in 2195 FSW

Microcracks in 2195 FSW
Micro-Cracking in the Dome FSW

- Weld is thickened, indicative of weld being harder than the parent metal
- Poor formability led to extensive cracking on the weld
- AGG is present in the weld after T8 heat treatment
Formability Enhancement is a key to Spun-Formed Dome Development
- Formability is the ability of a sheet metal to maintain its structural integrity while being plastically deformed into a shape.

Improvement in Formability Can be Made by Increasing Strain Hardening Exponent ("n") and strain rate sensitivity ("m")
- High strain hardening coefficient can help strain distribution and delay necking.
- High strain rate sensitivity can strengthen the necking zone and promote diffuse necking.
- These parameters are microstructure dependent.

A Formability Enhancing Novel Heat Treatment has been Developed at MSFC
- Show promise in enhancing formability by increasing the strain hardening exponent & strain rate sensitivity.
  - The novel heat treatment can equalize the weld/parent metal hardness.
  - And homogenous strain distribution without strain localization in the weld.
Determine the Strain Hardening Exponent “n” by Tensile Testing

True stress-strain curve

“n” determination

Strain hardening equation: \( \sigma = K\varepsilon^n \)

\[
\log \sigma = \log K + n \log \varepsilon \\
\Rightarrow n = \left( \frac{\partial \log \sigma}{\partial \log \varepsilon} \right)_\varepsilon
\]
Determine Strain Rate Sensitivity “m” by Tensile Testing

Generate true stress-strain curve with different strain rates

Strain rate sensitivity equation: \[ m = \left( \frac{\partial \ln \sigma}{\partial \ln \dot{\varepsilon}} \right)_\varepsilon \]

Plot log stress-strain rate for each grain size/anneal

Generate one chart for each grain size/anneal
The multi-step ramp rate controlled annealing process

Capable of improving the formability for 2195 Al-Li alloy by more than 50%

PW anneal 2

Advancing Side

Weld 1 & 3 are very different in the shape and size of weld nugget
Hardness Comparison after Post Weld Anneal

Thursday, June 23, 2011

Hardness across the weld after post weld anneal

- Weld 3 – anneal 3 has the highest hardness in the weld nugget
- Anneal 1 & 2 can equalize the weld/parent metal hardness
Sample with an extensometer on the specimen.

Cut plan & specimen configuration:

1. A 0.3” extensometer was used to record strain within the 0.5” gage section of the specimen.
2. A double reduced gage section was used to make sure the specimen necked and broke in the nugget of the weld.
The annealing parameters have profound effects on the strain hardening behavior. Anneal 2 has the most strain hardening effect; while anneal 3 leads to early strain softening.

</table>

1. Formability can be enhanced by using the novel heat treatment method.
2. PW anneal 2 produces the highest formability – highest forming range & “$n$”
3. PW anneal 3 produces the highest yield strength but the lowest formability
Comparison of Strain Hardening Exponent for Weld 1 & Weld 2

\[ \sigma = K \varepsilon^n \quad n = \left( \frac{\partial \ln \sigma}{\partial \ln \varepsilon} \right) \varepsilon \]

- Anneal 2 is very effective in increasing the strain hardening exponent
- More than 50% increase in the strain hardening exponent can be achieved with anneal 2
- Drastic reduction in strain hardening exponent after anneal 3 for weld 3
Analysis of Failed Tensile Samples (Weld 3)

Weld 3 – anneal 3
More localized necking

Greater reduction in area

Weld 3 – anneal 2
More uniform necking

Smaller reduction in area

Anneal 2 can homogenize strain distribution and prevent localized necking.
True Stress/True Strain Curves – Effects of Strain Rate & Anneal

Weld 3 – anneal 3

- Higher strain rate leads to higher strain hardening exponent for anneal 2
- Anneal 2 has higher strain hardening effect; while anneal 3 leads to early strain softening
- Strain softening observed in anneal 3 is a sign of poor formability

Weld 3 – anneal 2

- No strain softening below 25% strain
Strain Rate Sensitivity Comparison – Effects of Strain Rate & Anneal

- Anneal 3 increases the strain rate sensitivity at lower strain level
- Stain rate sensitivity turns negative at higher strain level & higher strain rate for anneal 3
- Negative strain rate sensitivity would accelerate necking & decrease formability
**Summary of the Formability Study Findings**

- **Demonstrated feasibility to increase strain hardening exponent by using the novel annealing process**
  - The current post weld anneal (anneal 3) resulted in low “n”
  - This is the reason why the FSW is susceptible to cracking during spin forming

- **The formability enhancing novel heat treatment is promising**
  - The “n” can be increased by more than 50%
  - Forming range and ductility also increase significantly
  - The “m” can be increased in the higher strain rate and higher strain regions
    - Capable of promoting more homogeneous forming strain distribution

- **Anneal 2 will be recommended for spin forming the cryogenic domes**
  - Can lead to significant increase in both “n” and “m” – higher formability

---

![Image: Weld cracking]

Low weld ductility problem can be solved by anneal 2
Additional Development Activities at MSFC

- **Develop welding parameters that can produce favorable weld microstructure for spin forming**
  - To enhance formability & mitigate AGG in the weld

- **Continue tensile testing to determine the strain rate sensitivity**
  - Another indicator of formability, higher strain rate sensitivity can enhance formability by defusing necking

- **Develop post-forming heat treatment (SHT+stretching+aging) that can mitigate AGG**
  - Looking into fast ramp rate heating methods and using favorable weld microstructure
