Everyone who works in the field of TPS.
Outline

- Introduction
- Thermal Protection Materials and Systems (TPS)
  - Reusable materials
  - Sharp leading edges (Ultra high temperature ceramics (UHTCs))
  - Ablative materials
  - New materials under development
- Characterization of TPS for Performance and Design
- A Tale of Two Heat Shields
  - Recent Uses and Development of Heat Shields and Materials Issues
Introduction

• NASA Ames focused on:
  – Qualifying and certifying TPS for current missions
  – Developing new TPS for upcoming missions

• Approaches to TPS development differ with risk — crewed vs. robotic missions:
  – Crewed
    • Loss of life must be avoided
    • What must be done to qualify and certify TPS?
  – Robotic missions
    • Can take more risk
    • But scientific knowledge can be lost too

• Goal for all TPS is efficient and reliable performance
• Need to understand materials to enable design and use
Thermal Protection Systems

- Protect vehicle structure and contents (people and things) from the heat of entry through an atmosphere
- Rely on materials response to environment
- Response depends on
  - Material properties
  - Configuration of the system
  - Specific conditions (heat flux, pressure, flow)

One size does not fit all!

Different TPS for different vehicles, location on vehicles, and mission conditions
Reusable vs. Ablative TPS

![Graph showing comparison between reusable TPS and ablative TPS](image-url)
Insulative TPS

*Energy management through storage and re-radiation — material unchanged*

When exposed to atmospheric entry heating conditions, surface material will heat up and reject heat in the following ways:

- Re-radiation from the surface and internal storage during high heating condition
- Re-radiation and convective cooling under post-flight conditions
Ames-Developed Thermal Protection Materials Used on Shuttle

- TUFI/AETB Tile
- AIM-22 Tile
- FRCI-12 Tile
- RCG Coating
- AFRSI Blanket
- Gap Fillers
Reusable TPS: Tiles

- Effort started in 1970’s by ARC to provide NASA with TPS materials and processing expertise
- Insulation materials used to protect the aluminum sub-structure of the shuttle.
- High purity silica, aluminoborosilicate, and alumina fibers
- LI-900, FRCI-12, AETB-8
- Open porous structure
- Used on over 100 shuttle missions

Tiles are heterogeneous with regions of low density and clumps of fibers with some nonfibrous inclusions
Reusable TPS: Coatings

RCG: Reaction Cured Glass
TUFI: Toughened Unipiece Fibrous Insulation

“Space Shuttle Tile”

- Silica-based fibers
- Mostly empty space - >90% porosity

RCG Coating

- RCG is a thin dense high emittance glass coating on the surface of shuttle tiles
- Poor impact resistance

TUFI Coating

- TUFI coatings penetrate into the sample
- Porous but much more impact resistant system
Shuttle Flight Testing of LI-900/RCG vs AETB-8/TUFI in Base Heatshield

TUFI/AETB-8 Tiles Undamaged After Three Flights
Development of Advanced TUFROC TPS
(Toughened Unipiece Fibrous Oxidation Resistant Ceramic)

- Developed TUFROC for X-37 application
- Advanced TUFROC developed recently
- Currently transferring technology to Boeing
- System parameters:
  - Lightweight (similar to LI-2200)
  - Dimensionally stable at surface temperatures up to 1922 K
  - High total hemispherical emittance (0.9)
  - Low catalytic efficiency
  - In-depth thermal response is similar to single piece Shuttle-type fibrous insulation
X-37B after Landing

TUROC is on Leading Edges

Insulators and UHTCs manage energy in different ways:

- Insulators store energy until it can be eliminated in the same way as it entered.
- UHTCs conduct energy through the material and reradiate it through cooler surfaces.

\[ \dot{q}_{\text{conv}} = \dot{q}_{\text{rad}} + \dot{q}_{\text{cond}} \]

Ultra High Temperature Ceramics (UHTCs): A Family of Materials

- Borides, carbides and nitrides of transition elements such as hafnium, zirconium, tantalum and titanium
- Some of highest known melting points
- High hardness, good wear resistance, good mechanical strength
- Good chemical and thermal stability under certain conditions
  - High thermal conductivity
  - Good thermal shock resistance
- The microstructure of UHTCs clearly shows their composite nature
  - Distribution of material phases
  - Flaw size and distribution
Energy management through material consumption

When exposed to atmospheric entry heating conditions, material will pyrolyze (char), and reject heat in the following ways:

- Pyrolysis of polymer
- Blowing in boundary layer
- Formation of char layer and re-radiation
PICA Processing

Carbon Fiberform™

Phenolic Resin

Resin Impregnation

PICA: Fiberform™ with phenolic resin

PICA Arc Jet Model

Drying Cycle

Phenolic Resin

PICA Arc Jet Model
PICA Background

- Phenolic Impregnated Carbon Ablator (PICA) was an enabling TPS material for the Stardust mission where it was used as a single piece heatshield.
- PICA has the advantages of low density (~0.27 g/cm³) coupled with efficient ablative capability at high heat fluxes.
- PICA is the primary heatshield for Mars Science Lab (MSL) and SpaceX’s Dragon vehicle in a tiled configuration.
Carbon Phenolic TPS

• Carbon Phenolic TPS
  – 1960s: fully dense (1.45-1.5 g/cm³) carbon phenolics were optimized
  – only materials available for use at very high heat fluxes and high pressure conditions, yet the least favorable in terms of density
• Carbon phenolic material made from carbon fiber weaves fully infiltrated with phenolic resin
• Current effort to investigate approaches to fabricating carbon phenolic materials
  – Issues with fiber supplies
• Carbon phenolic TPS was used on Galileo heat shield for very demanding entry into Jupiter’s atmosphere
What are Rigid, Conformable and Flexible Ablative Materials?

- **Rigid** – fabricated in a rigid form and usually applied in a tiled configuration to a rigid substructure
- **Conformable** – fabricated in a flexible form and shaped to a rigid substructure; final form may be rigid or compliant
- **Flexible** – fabricated and used in a flexible form, where flexibility is an essential component of the heatshield, e.g., deployable systems, stowable systems
- **Woven** – can be any of the above
Conformable/Flexible Ablators

- Fibrous substrate, such as felt, woven cloth
- Matrix of various resins and fillers
- Flexible/conformable ablators have significant design, system integration, and performance advantages compared to rigid ablators
  - Manufacturability
  - Reduction in piece-parts
  - Ease of assembly
  - Enables larger diameter aeroshells
  - Eliminates gap and seam issues (thermo-mechanical, aero-physics phenomena)
Families of Ablators Under Development

- **Rigid Ablators**
  - Advanced PICA-like ablators
  - Graded Ablators

- **Conformable Ablators**
  - Conformable PICA

- **Flexible Ablators**
  - Flexible PICA
  - Flexible SIRCA

- **Woven TPS**
  - Mid density TPS
  - Carbon phenolic replacement
What is the 3D Woven TPS concept?

An approach to the design and manufacturing of **ablative** TPS by the combination of weaving precise placement of fibers in an optimized 3D woven manner and then resin transfer molding when needed.

- Ability to design TPS for a specific mission
- Tailor material composition by weaving together different types of fibers (e.g. carbon, ceramic, glass, polymeric)
- One-step process for making a mid-density dry woven TPS
- Ability to infiltrate woven structure with a polymeric resin to meet more demanding thermal requirements
Characterization of TPS

Why characterize materials so extensively?
– Evaluate performance
– Select appropriate materials
– Verify manufacturing reliability
– Enable modeling of behavior
– Design system/heatshield
– Correlate processing and properties to improve materials
Manufacturing Variability

• Real-world manufacturing processes have inherent variability.
  – These variations can lead to scatter in the material properties.

• Necessary to quantify allowable lot-to-lot and in-lot variability of properties.
  – This may also include acceptable flaw and inclusion size.
Example: Ablator Properties

- Evaluating:
  - Virgin/char strength
  - Recession rate
  - Thermal conductivity

- Evaluating the interconnection between properties
  - Tradeoffs
  - Greater density = greater strength, but generally increased thermal conductivity
Material Properties

- Thermal properties
  - Thermal conductivity, specific heat, thermal expansion
- Physical properties
  - Density, hardness, emissivity
- Mechanical properties
  - Strength, elastic modulus, toughness
- Properties may vary with temperature and/or pressure (porous materials)
- Microstructure depends on processing and composition
## Properties for Modeling and Design of Ablators

### Thermal Response Model
- Density (virgin/char)
- Thermal Conductivity (virgin/char)
- Specific Heat (virgin/char)
- Emissivity & Solar Absorptivity (virgin/char)
- Elemental Composition (virgin/char)
- Thermal Gravimetric Analysis
- Porosity & Gas Permeability
- Heat of Combustion (virgin/char)
- Heat of Pyrolysis

### Thermal Structural Analysis
- Tensile: strength, modulus, strain to failure
- Compressive: strength, modulus, strain to failure
- Shear: strength, modulus, strain to failure
- Poisson’s Ratio
- Thermal Expansion (virgin/char)
- TPS/Carrier System Tests
  - Tensile strength
  - Shear strength
Process for Characterizing Ablators

Produce Material
Flight-like production, not model material
Consider mission environments

Evaluate Material’s Variability
NDE recommended
Insight into construction is critical to determine likely challenges

Determine Appropriate Testing Techniques
May depend on material’s density and construction
4 cm honeycomb not represented by a 1 cm coupon

Determine Quantity and Sampling Scheme
Influenced by material variability & project scope

Execute Testing & Evaluate Data
Selection of Appropriate Material

- **Historical approach:**
  - Use heritage materials: “It’s worked before…”
  - Risk-reduction strategy
  - Limited number of flight-qualified ablative materials
  - Different vehicle configurations and reentry conditions (need to qualify materials in relevant environments)

- As missions become more demanding, we need higher capability materials — necessary to have a robust research and development program
  - **Reusable and ablative materials are both needed**
  - Must test materials in relevant environments
  - Provide path for insertion/use of new materials
Technology Readiness Levels (TRLs)

- TRL 9: Actual system "flight proven" through successful mission operations
- TRL 8: Actual system completed and "flight qualified" through test and demonstration (Ground or Flight)
- TRL 7: System prototype demonstration in a space environment
- TRL 6: System/subsystem model or prototype demonstration in a relevant environment (Ground or Space)
- TRL 5: Component and/or breadboard validation in relevant environment
- TRL 4: Component and/or breadboard validation in laboratory environment
- TRL 3: Analytical and experimental critical function and/or characteristic proof-of-concept
- TRL 2: Technology concept and/or application formulated
- TRL 1: Basic principles observed and reported

A Tale of Two Heatshields

• 2 Vehicles
  – CEV/Orion/MPCV
  – Mars Science Lab (MSL)

• 2 destinations
  – Earth from the moon
  – Mars from Earth

• 2 materials
  – PICA
  – Avcoat
MPCV (Orion) TPS Requirements

- Multi-purpose Crew Vehicle (MPCV) Lunar Direct Return (LDR) conditions:
  - 11 km/s atmospheric entry
  - peak heat rate > 1000 W/cm²

- MPCV Low Earth Orbit (LEO) return conditions:
  - 8 km/s atmospheric entry
  - peak heat rate > 150 W/cm²

- Early TPS development work focused on PICA for this application
Phenolic Impregnated Carbon Ablator (PICA) was an enabling TPS material for the Stardust mission (sample return from a comet) where it was used as a single piece heatshield.

- **PICA reached TRL9 for this application and configuration**

- PICA has the advantages of low density (~0.27g/cm³) coupled with efficient ablative capability at high heat fluxes

- **As-flown PICA was characterized and compared to model predictions**

Sample return capsule post-flight with PICA as the forebody TPS. (0.8m diameter)
From PICA ……..

- PICA had heritage…for Stardust
  - Needed development effort for new applications
- PICA was to be used in a tiled configuration
  - Tiles require gap fillers or a way to deal with gaps
  - PICA is a rigid material with a relatively low strength and strain to failure
  - Risk analysis and design indicated that many small tiles would be required, increasing the number of gaps.
- PICA was extensively characterized and considerable effort was put into scale-up and manufacturing
Avcoat was used on the Apollo vehicles: “heritage” material.

- Consists of a honeycomb filled with an ablative mixture.
- Reduces gaps.
- Complex material requiring hand assembly.
- Not made for many years.

Before and after Avcoat arc jet models.
Heatshield Comparison

**PICA Acreage TPS**

Layout:
- 440 tiles
- 133 Unique Tile Planforms
- 832 Gap Fillers

RTV-SIP-RTV attachment to carrier structure

**Avcoat Acreage TPS**

Layout
- 18 Gore Honeycomb Panels
- 18 Shoulder Panels
- 1 Center Panel

Bond honeycomb to carrier structure and ablator filled-in and cured.
AVCOAT Process Steps

- 9 stages in AVCOAT process
- Complex processes require extensive characterization and understanding to
  - Ensure reliability/reproducibility
  - Prepare/maintain meaningful process specifications
Avcoat for MPCV Heatshield

- Avcoat construction schematic showing the various steps and processes involved in building the honeycombed ablator
- Red arrows indicate areas were process changes were implemented
Issues with “Heritage” Materials

- Know-how may be lost over time
- Materials/components may no longer be available
- Environmental/safety regulations may not allow the use of certain processes
- Recreation of materials can be time and money-consuming
  - $25+million and 5 years has been spent on recreating Avcoat
- Is it really “Avcoat”?
Meanwhile, Mars Science Lab in Development

- MSL was being fabricated simultaneously with CEV/Orion (MPCV)
- Initial choice for a heatshield TPS was SLA-561V, a heritage honeycomb-based material from Lockheed
- SLA-561V was used on all previous NASA Mars entry missions
- However, MSL was much larger …..
Change of TPS Late in the Game

- Original choice of TPS did not pass shear tests
- Needed to use a more capable TPS
- PICA was chosen
- Previous/ongoing development of PICA for CEV/Orion

Availability of data/processes critical in enabling the heat shield material to be qualified, certified and fabricated in time (18 months)

Instrumentation

- All atmospheric entries are essentially “experiments” from which we should gather data
- Data used to validate models and understand materials behavior better
- MSL was instrumented
  - MEDLI: Mars Entry Descent Landing Instrumentation
Importance of MSL Instrumentation

- MEDLI is the most extensive ablative heat shield instrumentation suite since Apollo
  - 7 pressure sensors, 26 near surface and in-depth thermocouples, 6 isotherm sensors
- Data will be used to validate and improve Mars entry aerothermodynamic and TPS response models
- Better models mean TPS safety margin can be reduced and science payload increased
Conclusions

• Two main classes plus specialized materials
  – Insulating, e.g. space shuttle tiles
  – Ablators for higher heat fluxes
  – High temperature materials and composites
  – New materials under development for new missions – woven, conformable, etc.
• TPS needs to fit the application—location on vehicle, expected environment
• Heritage materials may not always be heritage
• Need to gain full data value from flights/experiments: instrumentation is key
• Critical to characterize materials and archive data
  – For selecting appropriate material
  – To ensure material demonstrates desired behavior
  – To have materials ready for new missions

Goal of all TPS is reliable and efficient performance!
