The In-Space Propulsion Technology (ISPT) program has been developing in-space propulsion technologies that will enable or enhance NASA robotic science missions. The ISPT program is currently developing technology in four areas that include Propulsion System Technologies (Electric and Chemical), Entry Vehicle Technologies (Aerocapture and Earth entry vehicles), Spacecraft Bus and Sample Return Propulsion Technologies (components and ascent vehicles), and Systems/Mission Analysis. Three technologies are ready for flight infusion: 1) the high-temperature Advanced Material Bipropellant Rocket (AMBR) engine providing higher performance; 2) NASA’s Evolutionary Xenon Thruster (NEXT) ion propulsion system, a 0.6-7 kW throttle-able gridded ion system; and 3) Aerocapture technology development with investments in a family of thermal protection system (TPS) materials and structures; guidance, navigation, and control (GN&C) models of blunt-body rigid aeroshells; and aerothermal effect models. Two component technologies that will be ready for flight infusion in the near future will be Advanced Xenon Flow Control System, and ultra-lightweight propellant tank technologies. Future focuses for ISPT are sample return missions and other spacecraft bus technologies like: 1) Mars Ascent Vehicles (MAV); 2) multi-mission technologies for Earth Entry Vehicles (MMEEV) for sample return missions; and 3) electric propulsion for sample return and low cost missions. These technologies are more vehicle-focused, and present a different set of technology infusion challenges. While the Systems/Mission Analysis area is focused on developing tools and assessing the application of propulsion technologies to a wide variety of mission concepts. These in-space propulsion technologies are applicable, and potentially enabling for future NASA Discovery, New Frontiers, and sample return missions currently under consideration, as well as having broad applicability to potential Flagship missions. This paper provides a brief overview of the ISPT program, describing the development status and technology infusion readiness of in-space propulsion technologies in the areas of electric propulsion, aerocapture, Earth entry vehicles, propulsion components, Mars ascent vehicle, and mission/systems analysis.

I. Introduction

Missions carried out for the Planetary Science Division (PSD), of NASA's Science Mission Directorate, seek to answer important science questions about our Solar System. To enable or significantly enhance PSD's future planetary science missions, the In-Space Propulsion Technology (ISPT) program is developing critical propulsion, entry vehicle, and other spacecraft and platform subsystem technologies. ISPT focuses on the development of new enabling technologies that cannot be reasonably achieved within the cost or schedule constraints of mission development timelines.

Over time the focus of ISPT investments have evolved. Since 2001, the ISPT program has been developing in-space propulsion technologies that will enable and/or benefit near and mid-term NASA robotic science missions by significantly reducing cost, mass, risk, and/or travel times. ISPT technologies will help deliver spacecraft to PSD's future destinations of interest. In 2009, the ISPT program was tasked to start development of propulsion-related technologies that would enable future sample return missions. In 2012, the development of other spacecraft bus technologies is starting to be added to ISPT's technology development portfolio.

The ISPT program aims to develop technologies in the mid TRL range (TRL 3 to 6+ range) that have a reasonable chance of reaching maturity in 4–6 years. The objective is to achieve technology readiness level (TRL) 6 and reduce risk sufficiently for mission infusion. ISPT strongly emphasizes developing propulsion products for NASA flight missions that will be ultimately manufactured by industry and made equally available to all potential users for missions and proposals.

The ISPT program is currently developing technology in four areas. These include Propulsion System Technologies (Electric and Chemical), Entry Vehicle Technologies (Aerocapture and Earth entry vehicles), Spacecraft Bus and Sample Return Propulsion Technologies (components and ascent vehicles), and Systems/Mission Analysis. These in-space propulsion technologies are applicable, and potentially enabling for scientific missions.
future NASA Discovery, New Frontiers, and sample return missions currently under consideration, as well as having broad applicability to potential Flagship missions. This paper provides a brief overview of the ISPT program, describing the planning and development status of in-space propulsion technologies in the areas of electric propulsion, aerocapture, Earth entry vehicles, propulsion components, Mars ascent vehicle, and mission/systems analysis. For more background on ISPT, please see Ref. 1, 2, 3, 4, 5.

II. Technology Relevance

The ISPT priorities and products are tied closely to the science roadmaps, the SMD’s science plan, and the decadal surveys. ISPT therefore emphasizes technology development with mission pull. ISPT started developing technologies in 2002 that were applicable to Flagship missions. In 2006 after the Solar System Exploration (SSE) Roadmap was released, technology investments evolved and were focused on technologies that would also be applicable to New Frontiers and Discovery competed missions. To respond to this focus, investments in aerocapture (the use of aerodynamic drag for orbit capture) and electric propulsion continued to be a priority, but the refocus activity also recommended a long-life lower-power Hall electric propulsion system aimed at Discovery-class missions.

In March of 2011 the Planetary Science Decadal Survey was released, and provided guidance for ISPT’s future technology investments. This Decadal Survey made many references to ISPT technologies that were initiated in the previous decade such as aerocapture, NEXT, AMBR, and advancements made in the areas of astrodynamics, mission trajectory and planning tools. This Decadal Survey validated the technology investments ISPT has made over the last 10 years, and it provides ISPT with a new focus for the next decade.

The Decadal Survey Committee supported NASA developing a multi-mission technology investment program that will “preserve its focus on fundamental system capabilities rather than solely on individual technology tasks.” They highlighted the NEXT system development as an example of this “integrated approach” of “advancement of solar electric propulsion systems to enable wide variety of new missions throughout the solar system.” The Survey members made a recommendation for “making similar equivalent systems investments” in advanced solar array technology and aerocapture. In the Decadal Survey Report, the importance of developing those system technologies to TRL 6 was discussed.

One recommendation from the Decadal Survey Committee was for “a balanced mix of Discovery, New Frontiers, and Flagship missions, enabling both a steady stream of new discoveries and the capability to address larger challenges like sample return missions and outer planet exploration.” These broad mission needs would in turn require a balanced set of multi-mission technologies and integrated system capabilities. The Committee acknowledges that a “robust Discovery and New Frontiers Program would be substantially enhanced by such a commitment to multi-mission technologies.” Flagship mission technology needs were also identified for a Mars sample return mission, and for a number of outer planets.

III. Propulsion System Technologies

ISPT’s propulsion system technology investments are being made in the areas of Solar Electric Propulsion (SEP) and advanced chemical propulsion. SEP is both an enabling and enhancing technology for reaching a wide range of targets. Several key missions of interest: sample return, small body rendezvous, multi-rendezvous, Titan/Saturn System Mission (TSSM), Uranus Orbiter w/Probe, etc., require significant post-launch ΔV and therefore can benefit greatly from the use of electric propulsion. High performance in-space propulsion can also enable launch vehicle step down; significantly reducing mission cost. The performances of the electric propulsion systems allow direct trajectories to multiple targets that are otherwise infeasible using chemical propulsion. The technology allows for multiple rendezvous missions in place of fly-bys, and as planned in the Dawn mission, can enable multiple destinations. SEP offers major performance gains, moderate development risk, and significant impact on the capabilities of new missions. ISPT’s approach to the development of chemical propulsion technologies is primarily the evolution of component technologies that still offers significant performance improvements relative to state-of-art technologies. The investments focus on items that would provide performance benefit with minimal risk with respect to the technology being incorporated into future fight systems.

A. NASA’s Evolutionary Xenon Thruster (NEXT)

Current plans include completion of the NASA’s Evolutionary Xenon Thruster (NEXT) Ion Propulsion System targeted at Flagship, New Frontiers and demanding Discovery missions. The GRC-led NEXT project was competitively selected to develop a nominal 40-cm gridded-ion electric propulsion system. The objectives of this development were 1) to improve upon the state-of-art (SOA) NASA Solar Electric Propulsion Technology
Application Readiness (NSTAR) system flown on Deep Space-1 and Dawn, 2) to enable flagship class missions by achieving the performance characteristics listed in Table 1.

The ion propulsion system components developed under the NEXT task include the ion thruster, the power-processing unit (PPU), the feed system, and a gimbal mechanism. The NEXT project is developing prototype-model (PM) fidelity thrusters through the Aerojet Corporation. In addition to the technical goals, the project has the goal of transitioning thruster-manufacturing capability with predictable yields to an industrial source. To demonstrate the performance and life of the NEXT thruster, a test program is underway. The NEXT PM thruster completed a short-duration test in which overall ion-engine performance was steady with no indication of performance degradation. A NEXT PM thruster has passed qualification level environmental testing. As of May 31, 2012 the Long Duration Test (LDT) of the NEXT engineering model (EM) thruster achieved over 723-kg xenon throughput, $2.76 \times 10^6$ N-sec of total impulse, and over 41,468 hours at multiple throttle conditions. (Fig. 1) The NEXT LDT wear test is demonstrating the largest total impulse ever achieved by a gridded-ion thruster. ISPT funding for the thruster life test continues through FY12 and into FY14. The goal is to demonstrate thruster operation through the anticipated first failure mode (structural failure of the ion optics) which is anticipated at 750 kg of xenon throughput at full power conditions. The current projection for screen grid penetration is 800 kg, which depending on the relative rates of the pit and groove erosion of the screen grid may or may not represent the end-of-life condition for the NEXT thruster. A post-test inspection of the hardware will be conducted in FY14.

Figure 1. Next Thruster Total Throughput versus representative mission requirements.
One of the challenges of developing the NEXT ion propulsion system was the development of the Engineering Model PPU. The demanding test program has flushed out a number of part problems that required extensive investigations to resolve and implement corrective actions.\textsuperscript{12} It should be noted that such part problems are not unique in a technology development phase, and can still be experienced in the transition-to-flight hardware development phase. Technology development projects like NEXT are trying to identify and mitigate these kinds of issues, before the PPU moves into a flight development phase.

One of the recent PPU part problems was the catastrophic failure of the multi-layer ceramic (MLC) capacitor in multiple beam power supplies. The investigation process required a large team that investigated all branches of the fault tree. The corrective actions identified that a custom-built MLC had piezoelectric properties that made it susceptible to an oscillating current in the beam supply circuit. The corrective actions in this case were to replace the custom-build MLC capacitor as well as to eliminate the oscillating current. Recently, another part problem was uncovered, which manifested itself as a shorted diode. The diagnosis was that a void in the printed circuit board contributed to an overvoltage condition on the diode which caused it to short. This conclusion was confirmed with x-ray inspection of the printed circuit board. The corrective actions MLC capacitor issues were implemented in the EM PPU, and this resolved the problems. The PPU is currently being refurbished to complete the planned test matrix, which includes PPU-thruster integration testing, electromagnetic interference testing, and breadboard digital control interface unit (DCIU) integration tests. The NEXT PPU is shown in Fig. 2.

An area in which further NEXT work has been needed is that of precise plume, particle, and field characterization. A non-reimbursable Space Act Agreement (SAA) was drafted by NASA and The Aerospace Corporation to establish a collaborative measurement program intended to examine the plume, particle, and field environments of the latest generation NASA ion propulsion technology. A series of measurements has been completed to verify basic characteristics of NEXT operation and expand on the available public-domain and internal databases regarding NASA technology and its potential use on non-NASA spacecraft systems.\textsuperscript{13} Figure 3 shows the NEXT thruster installed in the vacuum facility at The Aerospace Corporation. Among the work elements planned are in-depth EMI/EMC, plume particle and plasma probe, optical emission and laser diagnostic measurements. This work is of considerable relevance to future spacecraft integration of the subject thrusters.

The NEXT evaluation at Aerospace also includes measurement of ion beam flux and divergence, charge state ratios, charge exchange ion flux, plume optical emission spectrum and absolute flux, radio frequency and microwave absolute emission spectrum plus time-domain emissions, carrier wave attenuation and phase effects, plume erosion and molybdenum contamination effects, absolute thrust and thrust correction factors. Plume characterization tests with the NEXT ion thruster were performed using the EM and PM thrusters. Examinations of the beam current density and xenon charge-state distribution as functions of position on the accelerator grid have been completed.\textsuperscript{14} The angular dependence of beam current was measured at intermediate and far-field distances to assist with plume modeling and to evaluate the thrust loss due to beam divergence. Thrust correction factors were derived from the data.\textsuperscript{14} Transmission and phase noise measurements were made through the plume of an EM NEXT ion thruster.\textsuperscript{15} Attenuation measurements were taken at multiple operating points at frequencies between 1 and 18 GHz. Attenuation was observed between 1 and 3 GHz and scaled with plasma density.\textsuperscript{15} Phase noise spectra were also taken. Direct thrust measurements have been made on the NEXT PM ion thruster using a standard pendulum style thrust stand constructed specifically for this application.\textsuperscript{16,17} Values have been obtained for the full 40-level throttle table as well as for a few off-nominal operating conditions.\textsuperscript{16,17}

A particle-based model with a Monte Carlo collision model has been developed by Wright State University (WSU) to study the plasma inside the discharge model of the generic ion thruster. This model tracks five major particle types inside the discharge chamber in detail: xenon neutrals, singly and doubly charge xenon ions.
secondary electrons and primary electrons.\textsuperscript{18} Both electric and magnetic field effects are included in the calculation of the charged particle’s motion. Validation of this computational model has been made with comparisons to the NSTAR discharge chamber. Comparison of numerical simulation results with experimental measurements were found to have good agreement.\textsuperscript{18} The model has been applied to the NEXT discharge chamber design at multiple thruster operating conditions.\textsuperscript{19,20,21,22,23}

Additional information on the NEXT system can be found in the NEXT Ion Propulsion System Information Summary in the New Frontiers and Discovery Program libraries.\textsuperscript{21,24,25}

B. Electric Propulsion for Sample Return and Discovery-class Missions

ISPT is investing propulsion technologies for applications to low-cost Discovery-class missions and Earth-Return Vehicles for large and small bodies. The first example leverages the development of a High-Voltage Hall Accelerator (HIVHAC) thruster into a lower-cost electric propulsion system.\textsuperscript{2,26} HIVHAC is the first NASA electric propulsion thruster specifically designed as a low-cost electric propulsion option. It targets Discovery and New Frontiers missions and smaller mission classes. The HIVHAC thruster does not provide as high a maximum specific impulse as NEXT, but the higher thrust-to-power and lower power requirements are suited for the demands of some Discovery-class missions and sample return applications.

Advancements in the HIVHAC thruster include a large throttle range from 0.3–3.9kW allowing for a low power operation. It results in the potential for smaller solar arrays at cost savings, and a long-life capability to allow for greater total impulse with fewer thrusters. The benefits include cost savings with a reduced part count and less-complex lower-cost propulsion system.

Wear tests of the NASA-103M.XL thruster validated and demonstrated a means to mitigate discharge channel erosion as a life-limiting mechanism in Hall thrusters. The thruster, operated in excess of 5500 hours (115 kg of xenon throughput) at a higher specific impulse (thruster operating voltage) as compared to SOA Hall thrusters.

Components for two Engineering Development Units (EDU-1) thrusters were designed and fabricated. Preliminary performance mapping of the EDU-1 thruster at various operating conditions was performed at NASA Glenn Research Center (GRC), Fig. 4 and 5.\textsuperscript{2,26} The EDU-1 thruster hardware was operated in vacuum test environments for operations and performance assessments. The results indicated that several design changes were needed to resolve problems with thermal design, boron-nitride advancement mechanisms, magnetic topology, and high-voltage isolation. A list of rework items was compiled and design corrections were identified and evaluated by either analysis and/or test. The design improvements were implemented in a reworked engineering model design, which is designated as EDU-2. Vacuum Facility 12 (VF-12) was used to conduct the official performance acceptance test (PAT), given the pumping speed and resulting vacuum chamber background pressure. The results indicate that performance and operational requirements have met expectations, with significant improvement to the thermal margins of key components. Vibration testing was completed with performance tests conducted both before and after vibration tests. The HIVHAC EMR thruster was successfully vibrated to approximately 11.5 g in three axes, which were consistent with the specifications used to qualify the NASA Evolutionary Xenon Thruster ion thruster. Preliminary visual inspection of the thruster indicates that the thruster passed the vibration testing with no visual damage evident and no change in thruster performance was measured. The HIVHAC EDU-2 thruster advancement mechanism on inner and outer boron nitrate channels was successfully demonstrated immediately after thruster hot-fire operation in VF-12. The advancement mechanism showed smooth advancement of both channels as a full qualification vibration test.
post-test validation of the mechanism. The actuation test was conducted immediately following thruster shutdown, assuring high-temperature conditions within the thruster. In the future, the test sequence will include performance acceptance tests, the remaining thermal vacuum environmental tests, and a long duration wear test in FY13. Current plans include the design, fabrication and assembly of a full Hall propulsion system that can meet a variety of Discovery and Earth Return Vehicle needs.

In addition to the thruster development, the HIVHAC project is evaluating power processing unit (PPU) and xenon feed system (XFS) development options. These were developed under other efforts, but can apply directly to a Hall Propulsion system. The goal is to advance the TRL level of a Hall propulsion system to level 6 in preparation for a first flight.

The functional requirements of a HIVHAC PPU (Fig. 4) are operation over a power throttling range of 300 to 3,800 W, over a range of output voltages between 200 and 700 V, and output currents between 1.4 and 5 A as the input varies over a range of 80 to 160 V. A performance map across these demanding conditions was generated for one candidate option\textsuperscript{22,26} that is being developed through NASA Small Business Innovation Research (SBIR) Program. Beyond conventional feed system options, one option for feed systems that was demonstrated with the Hall thruster is the advanced xenon feed system developed by VACCO.

To continue to simplify and reduce the cost of the HIVHAC system, the ISPT program invested in its reliable, lightweight, and low-cost xenon flow control system.\textsuperscript{27} A follow-on contract was awarded to VACCO as a joint ISPT and Air Force effort to qualify a Hall system flow control module. This module would significantly reduce the cost, mass, and volume of a Hall thruster xenon control system while maintaining high reliability and decreasing tank residuals. This is the first time the ISPT program advanced a component technology to TRL 8 to further reduce the risk and cost of the first user. The new Hall module, shown in Fig. 6, completed its qualification program in June 2012. The module is then planned for inclusion in a HIVHAC thruster long duration wear test along with the SBIR PPU as an integrated string test of the HIVHAC system. A second flow control module unit (an acceptance tested flight unit) has been ordered and should be delivered in December 2012. A joint ISPT/Air Force team participated in a Preliminary Design Review (PDR) of the VACCO Smart Flow Control Module (SFCM) for infusion into a commercial spacecraft bus using electric propulsion. The module is expected to significantly reduce the xenon feed system complexity, cost, and cycle time. A Critical Design Review (CDR) is tentatively planned for August 2012. The delivery of first qualification test unit is anticipated in March 2013.

The Near-Earth Object (NEO) mission was evaluated, and the HIVHAC thruster system delivered over 30 percent more mass than the NSTAR system. The performance increase accompanied a cost savings of approximately 25 percent over the SOA NSTAR system. The Dawn mission was evaluated, and the expected HIVHAC Hall thruster delivered approximately 14 percent more mass at substantially lower cost than SOA, or decreasing the solar array provided equivalent performance at even greater mission cost savings.\textsuperscript{28}

The second technology example of a Sample Return Propulsion Technology is the BPT-4000 Hall thruster development. ISPT has invested in a life-test extension of the thruster to improve total impulse demonstrated capabilities. Under evaluation is the operation of this thruster design at higher operating voltages, which improve thruster specific impulse. There are mission studies that indicate that BPT-4000 is directly applicable to ERV and Discovery-class missions. For more HIVHAC information, see Ref. 28, 29.

\section*{C. Advanced Materials Bi-propellant Rocket (AMBR) Engine}

ISPT’s single largest investment within the advanced chemical propulsion technology area was the Advanced Materials Bipropellant Rocket (AMBR) engine (Fig. 7). Ref. 30 has a thorough description of the complete Advanced Chemical Propulsion effort that was concluded in 2009. The AMBR effort was awarded through a competitive process to Aerojet Corporation in FY2006. The AMBR engine is a high

A temperature thruster that aimed to address cost and manufacturability challenges of using iridium coated rhenium chambers. The project includes the manufacture and hot-fire tests of a prototype engine demonstrating increase performance and validating new manufacturing techniques.\textsuperscript{31} Performance testing was conducted on the AMBR engine in October 2008 and February 2009 with long duration testing in June 2009. The thruster demonstrated an $I_p$ of 333 seconds at 141 lbf thrust,\textsuperscript{31} which is the highest ever achieved for hydrazine/NTO (nitrogen tetroxide) propellant combination. The project completed vibration shock, and long-duration testing to raise the TRL to 6. Additional information is found in the AMBR information summary in the New Frontiers and Discovery program libraries.\textsuperscript{24,25,32}

IV. Entry Vehicle Technologies

A. Multi-Mission Earth Entry Vehicle (MMEEV)

The Multi-Mission Earth Entry Vehicle (MMEEV) is a flexible design concept. It can be optimized or tailored by any sample return mission, including lunar, asteroid, comet, and planetary (e.g. Mars), to meet that mission’s specific requirements. The Mars Sample Return (MSR) Earth Entry Vehicle (EEV) design, due to planetary protection requirements, is designed to be the most reliable space vehicle ever flown. It provides an effective foundation for many sample return missions. By leveraging common design elements, this approach can significantly reduce the risk and associated cost in development across all sample return missions.\textsuperscript{3}

Detailed studies show that to meet the stringent containment requirements for a Mars sample return mission, the MMEEV should possess three particular design attributes. First, the vehicle aerodynamics must be very well understood. This means utilizing a shape with extensive analysis, testing, and flight experience. The vehicle aerodynamics must also be “self-righting.” It needs to quickly stabilize itself in a heatshield-forward orientation in the event of perturbations. Second, the heat shield TPS needs to be robust enough to ensure a high level of reliability for both nominal and off-nominal (such as MMOD impacts) environments. (The reliability requirement has traditionally been thought to imply the use of heritage carbon phenolic TPS, which is limited in supply and manufacturability. NASA has held two workshops, in 2010 and 2012, to assess the availability of carbon phenolic and possible replacement materials. The forward path will depend on funding availability, and is not yet defined.) Third, the MMEEV has no parachute or other deployable drag device. Because of the reliability required, the capsule would already need to be designed to survive and safely contain the sample after an Earth impact in the event of a failure of the drag device.

The current MMEEV parametric configuration is presented in Fig. 8 (basic vehicle architecture), and Table 2 (parametric variables). Because each individual sample return mission may have a unique set of performance metrics of highest interest, the goal is to provide a qualitative performance comparison across a specified trade space. Each sample return mission can then select the most desirable design point to begin a more optimized design.

MMEBV performance studies will continue with the eventual integration of the MMEEV models into the “Multi-Mission Systems Analysis for Planetary Entry” (M-SAPE) Tool. This is a prototype, quick turn-around EDL analysis tool, originally developed in support of ISPT aerocapture studies. The M-SAPE tool contains low-, mid-, and high-fidelity models, and the user can specify the level of analysis to be performed. High-fidelity validated thermal protection system response models (FIAT) and trajectory simulation tools (POST) are incorporated into the baseline tool.\textsuperscript{33} Plans for the next two years of development include ground tests to validate additional tool modules, and training and tool dissemination to the user community. Recent (FY11-12) model developments and validation testing include thermal soak model

Figure 8. Basic MEEV architecture
development, foam impact tests, and spin tunnel testing.

Parametric preliminary thermal soak model was developed at NASA-Ames to understand the thermal environment of the returned sample canister after the vehicle undergoes the heat pulse and waits to be recovered. Samples from various comets, asteroids, and planets may have differing thermal requirements to preserve the science return. This allows various structural materials to be evaluated, and will help determine if active thermal control is needed for some missions. Feeding into the thermal soak model is actual test data on impact foams (as shown in Fig. 8). Several closed-cell foam candidates have been impact tested at NASA-Langley (Fig. 9) and are now undergoing material properties testing to determine their post-impact thermal characteristics. These parameters for various materials will be part of the closed-loop M-SAPE analysis capability. Finally, the stability and orientation characteristics of various capsule geometries will be verified via spin tunnel testing at NASA-Langley. This type of subsonic test allows almost free-flight without the interference of a sting, to verify low-speed aerodynamic properties. Scaled vehicle models with various aftbody configurations (i.e., payload sizes) will be tested in Summer 2012 to determine subsonic stability characteristics of the chute-less capsule.

The goal of this work is to provide validated tools for evaluating MMEEV designs from the conceptual level to high fidelity. Development and use of the capabilities will enable New Frontiers and Discovery missions to cost-effectively fly Earth Entry Vehicles that flight test the robust design features of the MSR EEV. This approach provides a built-in flight validation to help the MSR EEV to reach its high reliability, without the significant cost of a dedicated flight test. Although Science Mission Directorate management and the ISPT project team favor this approach, there are currently no manifested missions that use the MMEEV design.

B. Aerocapture

Aerocapture is the process of entering the atmosphere of a target body to obtain a change in velocity (∆V) from aerodynamic forces to slow down and capture the spacecraft in a planetary orbit. Aerocapture is the next step beyond aerobraking. Whereas aerobraking relies on multiple passes through the upper atmosphere (once a spacecraft is captured propulsively into a high ellipse) to reduce orbital energy, aerocapture (Fig. 10), maximizes the benefit from the atmosphere by capturing into a useful science orbit in a single pass. Aerocapture flies at a lower altitude where the atmosphere is more dense, and therefore the resultant drag and heating is higher than for aerobraking. An aeroshell is required to both protect the spacecraft from the environment, and provide an aerodynamic surface for control during the pass. Keys to successful aerocapture are accurate arrival state knowledge, validated atmospheric models, sufficient vehicle control authority (i.e. lift-to-drag ratio), and robust guidance during the maneuver. A lightweight thermal protection system and structure will maximize the aerocapture mass benefits. Aerocapture significantly reduces the chemical propulsion requirements of an orbit capture.

Aerocapture has shown repeatedly in detailed analyses to be an enabling or strongly enhancing technology for...
several targets with atmospheres, and ISPT has been investing to mature Aerocapture subsystems since 2001. The aerocapture project team continues to mature aerocapture components in preparation for a flight demonstration. Rapid aerocapture analysis tools are being developed and made available to the user community. The TPS materials developed through ISPT enhance a wide range of missions by reducing the mass of entry vehicles. The remaining gaps for technology infusion are efficient TPS for high-speed Earth return, Venus, Saturn, and Neptune. All of the other component technologies for an aerocapture vehicle are currently at TRL 5-6. This assessment of technology readiness is detailed in Ref. 35. The structures and TPS subsystems as well as the aerodynamic and aerothermodynamic tools and methods can be applied to planetary entry missions even if the aerocapture maneuver is not utilized.

Recent testing and development focused on maturing efficient rigid aeroshell systems. The low- and mid-density ablator systems (called “SRAM” and “PhenCarb” from Applied Research Associates, ARA) were matured by increasing the scale and complexity from the TPS subsystem to that of an aeroshell system with an underlying structure. The abiators were tested at both NASA Ames Research Center’s (ARC) arcjet and Sandia National Labs’ solar-tower facilities in the form of 5-in coupons, and 1-ft and 2-ft square flat panels. Both TPS families were applied to one-meter, 70 degree, high-temperature blunt body aeroshell structures from ATK to demonstrate manufacturability of a representative shape.

As flight aeroshells become larger (over 3 meters in diameter), it is more difficult to hand-pack them, as was done with the Apollo capsules and every successful Mars heatshield to date. ARA developed a modular TPS approach, in which large modules of TPS are pre-packed into honeycomb, cured, and precisely milled to fit the aeroshell structure. Because SRAM and PhenCarb are somewhat elastic, a small number of modules (less than ten) are needed to cover the aeroshell (compared to tens of PICA tiles used on MSL). Gaps between modules are packed with the same ablator and cured. The result is a seamless heatshield. To mature this approach, ISPT has manufactured a 2.65-meter (Discovery-class size) low-density heatshield (Fig. 11). The TPS is applied to the ATK 400 °C bondline structure. Lawrence Livermore National Laboratory (LLNL) scientists will perform a non-destructive scan of the completed aeroshell to mature diagnostic methods. Manufacturing at this scale will mature the high-temperature aeroshell system to TRL 5.

The SRAM TPS on the 2.65-meter article can also accommodate instrumented thermal plugs. These are similar to the plugs included on the Mars Science Laboratory as part of the MEDLI (MSL Entry, Descent and Landing Instrumentation) suite. The included sensors measure TPS recession with sub-millimeter accuracy. The sensors were developed at NASA ARC under ISPT funding. The instrumentation of entry systems to gather flight data is of primary importance to understand the system.
performance, environments, and vehicle requirements for future missions. During a cruise checkout in March 2012, all of the MSL sensor plugs were reading normally, and engineers look forward to flight data from Mars entry on August 5, 2012.

The precursor, or test unit, for the 2.65-meter modular SRAM aeroshell was a modular PhenCarb one-meter aeroshell. This unit underwent thermostructural testing at the Sandia National Labs solar tower facilities in March 2011 (Fig. 12). The unit was scanned by LLNL before and after the thermostructural testing.

Another effort to raise the TRL for TPS materials includes Space Environmental Effects (SEE) testing. Conducted at the Marshall Space Flight Center and the White Sands Test Facility (WSTF), this testing includes radiation exposure, cold soak, and 7 km/s micrometeoroid impact on the ISPT-matured TPS and hot structure materials for forebodies and backshells, to levels representative of a deep space mission. Following exposure to these environments, samples are arcjet tested to representative entry and aerocapture heat rates and loads, at NASA-Ames. Figure 13 shows an impacted SRAM backshell material before and after arcjet testing. Micrometeoroid cavity volumes pre- and post-test can be compared using laser and CT scanning techniques. The testing is expected to be complete in July 2012. Additional information on aerocapture technology developments can be found in the Discovery Program library, and in Ref. 36, 37, 38, 39, 40, 41.

V. Spacecraft Bus and Sample Return Propulsion Technologies

A. Mars Ascent Vehicle (MAV)

For many years, NASA and the science community asked for a Mars Sample Return (MSR) mission. There were numerous studies to evaluate MSR mission architectures, technology needs and development plans, and top-level requirements. Because of the challenges, technologically and financially of the MSR mission, NASA initiated a study to look at MSR propulsion technologies through the ISPT Program Office. The objective of the ISPT Program is to develop propulsion technologies that enhance or enable NASA science missions for the Planetary Science Division (PSD) by increasing performance while reducing cost, risk, and/or trip length. The largest propulsion risk element of the MSR mission is the Mars Ascent Vehicle (MAV). The current architecture for the MSR lander is to use the Mars Science Laboratory (MSL) entry, descent, and landing (EDL) system. Using the MSL sky crane concept places significant environmental, physical envelope and mass limitations on the MAV system options.

Beyond the limitations of the EDL system, the MAV has specific requirements to deliver the orbiting sample (OS) into an orbit suitable for the Earth Return Vehicle (ERV). Many of the subsystem requirements of the MAV are still to be determined, with many to be defined by the prime integrator during development. However, the driving top-level requirements of the MAV include:

1. The MAV shall deliver a 5kg, 16cm sphere (Sample Container), to a low Mars orbit.
2. The Mars orbit must achieve a periapsis greater than 460km and an apoapsis less than 580km with an inclination of 45° +/- 0.2°.
3. The MAV shall transmit both real-time and recorded engineering data to an orbiting asset with sufficient fidelity to discern root cause of failure or off-nominal performance.
4. The MAV must not require sub-centimeter center-of-gravity accuracy.
5. The MAV shall fit within the physical constraints of the Mars Science Laboratory (MSL) Entry Decent and Landing (EDL) system.
6. The MAV shall be single fault tolerance where appropriate.

Another challenge for the MAV is to meet the environmental requirements for the mission. The environmental
requirements include the Earth launch, transit within the cruise stage, the Mars EDL, and finally a long surface stay on Mars. The environments anticipated to influence the system design are the vacuum environment during cruise, the 15g quasi-static lateral load during EDL, and the diurnal temperature cycling, as low as −99°C during the surface stay. The thermal requirements necessitate a thermal enclosure or “igloo” in order to maintain practical lander power requirements. A detailed set of requirements and system design standards and guidelines has been established for all study participants to ensure comparable system capability and margins.43

Through the NASA Research Announcement (NRA) process, the ISPT program solicited MAV system designs and plans to initiate propulsion system development. Multiple contractors were selected to proceed in October of 2010 and efforts were initiated in February 2011. Awards were made to ATK, Lockheed Martin, and Northrop Grumman to develop MAV concepts using solid-solid, solid-liquid, and liquid-liquid 1st and 2nd stage propulsion systems respectively. During the NRA efforts, the contractors completed Principal Investigator (PI) led collaborative engineering designs of the MAV and will begin contract options to develop the required technologies in early FY12. Additionally, Firestar Technologies is working, under an SBIR, to develop a Nitrous Oxide Fuel Blend propulsion system applicable to the MAV.44 The results of the industry efforts indicate that while technology development remains, there are multiple paths to meet performance and requirements of the Mars Ascent Vehicle. The industry efforts and designs are documented in four 2012 IEEE Aerospace Conference papers.45,46,47,48 The baseline MAV concept design is shown in Fig. 14. The Government baseline design is pre-decisional and for understanding design trades and sensitivities, and does not represent any concept selection.

NASA performed system design studies with the Jet Propulsion Laboratory’s (JPL) Team-X and GRC’s COMPASS teams.45 The collaborative designs included a system level optimization using the industry designs and an internal “leveled” design to allow comparison of system mass, complexity, and maturity. The trades included the MAV support systems and lander impacts to minimize the total landed mass. The preliminary results of the studies indicate that the baseline solid-solid system appears to offer the lowest mass solution, but it may have challenges achieving the required orbit dispersion accuracies. The solid-liquid option has a slightly higher mass, imposing more thermal requirements on the lander, but can reduce dispersion errors. The liquid-liquid option has the highest mass growth potential due to its mass fraction relative to a solid motor, but requires the least lander resources and has very tight dispersions. The preliminary NOFBx system evaluation indicates it may be a competitive option, but is unlikely to offer a single stage to orbit solution with a lower mass than the two-stage solid.

Each of the MAV concepts was evaluated for risk and technology maturation and was recommended, primarily in the propulsion elements. The MAV NRA work initially focused on the key risks of the individual propulsion systems at the component level. The MAV project team expects to achieve a milestone in late FY12 to address the key risks of each option and determine the final viability of various concepts. If the most promising MAV concept(s) is viable with respect to mass, volume, and risks, an integrated propulsion stage demonstration would be the next step. If sufficient risk can be reduced through the technology development activities, the final step would be an engineering model MAV development with an objective of a vehicle terrestrial flight demonstration. However, the MAV technology development for the most part is on hold pending the completion of the Mars Program Planning Group (MPPG) activities. Some on-going MAV related studies are being completed, and a long-lead activity to assess the aging of solid rocket motor propellants under Mars environmental conditions (landing shocks and thermal cycling) will proceed until future decisions determine the future MSR architecture and MAV requirements.

B. Ultra-lightweight Tank Technology (ULTT)

ISPT invests in the evolution of component technologies that offer significant performance improvements without increasing system level risk. The ISPT Program invested in ultra-lightweight tank technology (ULTT) led by JPL. The ULLT efforts in the past focused on manufacturability and non-destructive evaluation of the lightweight tanks. The tank effort continues to validate defect-detection techniques to maintain NASA standard compliance for ultra-thin wall tanks. The follow-on potential is to develop and qualify positive expulsive ultra-lightweight tanks specifically for the MSL Sky Crane. The Mars Science Laboratory (MSL) Sky Crane, with large propellant tanks, is shown in Fig. 15.
The Sky Crane tanks offer mass savings on the order of 24 kg. This is dependent on the final tank wall thickness. The mass reduction would increase the landed mass capability of Sky Crane for a relatively low cost per kg. The Sky Crane Entry Descent Lander (EDL) system could be used again in a future Mars Sample Return (MSR) mission. Both are highly mass constrained. While this particular tank design will be qualified for the Sky Crane application (Fig. 16), the ultra-lightweight technology will be applicable for a wide range of future science missions. Propulsion tanks remain the highest dry-mass reduction potential within chemical propulsion systems. This technology would significantly push the state-of-the-art with the promise of a 2X improvement over conventional tank designs.

The development effort is divided into two main tasks: a Non-Destructive Inspection (NDI) task and the ultra-lightweight tank design/manufacturing/testing task. The NDI task completed an initial assessment of several NDI techniques, such as eddy-current and surface wave ultrasonic techniques. The results from the tests indicate that these techniques are adequate to find cracks as small as 0.003 inches in the titanium lining. The objective for the NDI task is to establish the crack size that can be detected consistently using these new methods. The ultra-lightweight tank development task would incorporate the NDI technique in the manufacturing and qualification of the new tank. In order for the tank design to be a success, the approach must demonstrate “safe life.” Safe life for non-toxic materials requires proving a design will leak-before-burst. Safe life for toxic liquids, like hydrazine, is more stringent. The NDI technique must be able to detect small cracks in the thin liners, then the NDI results need to be verified, by test, that worst-case crack growth will not grow to failure. An automated eddy current inspection technique has been developed and tested for the detection of small fatigue cracks in thin titanium panels. In this work, a commercially available eddy current probe was deployed on a motion control system in order to obtain high-resolution eddy current C-Scan images of 48 individual samples. A data processing technique was developed and deployed to enhance the flaw response and automate detection of crack-like indications in the samples. The noise floor of the inspection technique was calculated as three times the standard deviation of the eddy current response in the two unflawed control samples. The remaining 46 samples had fatigue cracks with estimated depths varying between 0.0021 and 0.0067 inches. All the fatigue crack panels registered crack-like indications at a level greater than three times the calculated noise floor. The improved detection capability promises to find 0.003 inch cracks reliably, which represents a 2X improvement over state-of-art (SOA) detection techniques. The new technique enables the manufacturing of composite-overwrapped titanium tanks with an anticipated 48 percent mass savings as compared to the heritage Sky Crane tank design. In parallel the ultra-lightweight development work will be completed through a contracted effort with ATK, the suppliers of the MSL tanks. The work will be divided into several phases: design, manufacturing and acceptance/qualification tests. The test phase will include cyclic testing of the flawed liner tank design to demonstrate leak-before-burst and safe life requirements. The design phase led to the Preliminary Design Review (PDR) was held in February 2012, and activities are progressing towards a Critical Design Review at the end of 2012.

VI. Systems/Mission Analysis

Systems analysis is used during all phases of any propulsion hardware development. The systems analysis area serves two primary functions:

1. to help define the requirements for new technology development and the figures of merit to prioritize the return on investment,
2. to develop new tools to easily and accurately determine the mission benefits of new propulsion technologies allowing a more rapid infusion of the propulsion products.
Systems analysis is critical prior to investing in technology development. In today’s environment, advanced technology must maintain its relevance through mission pull. Systems analysis is used to identify the future mission needs for decadal missions and Discovery design reference mission (DRMs). The mission studies identify technology gaps, and are used to quantify mission benefits at the system level. This allows studies to guide the investments and define metrics for the technology advancements. Recent systems analysis efforts include quantitative assessment of higher specific impulse Hall thrusters, higher thrust-to-power gridded-ion engines, and evaluation of monopropellant system anomalies to assess failure modes and potential mitigation options. In addition to informing project decisions, the mission design studies provide an opportunity to work with the science and user community.

The second focus of the systems analysis project area is the development and maintenance of tools for the mission and systems analyses. Improved and updated tools are critical to allow the potential mission users to quantify the benefits and understand implementation of new technologies. A common set of tools increases confidence in the benefit of ISPT products both for mission planners as well as for potential proposal reviewers. For example, low-thrust trajectory analyses are critical to the infusion of new electric propulsion technology. The ability to calculate the performance benefit of complex electric propulsion missions is intrinsic to the determination of propulsion system requirements. Improved mission design tools demonstrate the ability to enable greater science with reduced risk and/or reduced transit times. Every effort is made to have the ISPT program tools validated, verified, and made publicly available. Additional information on the ISPT tools is available at the ISPT website, http://spaceflightsystems.grc.nasa.gov/Advanced/ScienceProject/ISPT/LTTT/, including background information and instructions to request the software.

The ISPT office invested in multiple low-thrust trajectory tools that independently verify low thrust trajectories at various degrees of fidelity. The ISPT low-thrust trajectory tools (LTTT) suite includes Mystic, the Mission Analysis Low Thrust Optimization (MALTO) 9+6 program, Copernicus, and Simulated N-body Analysis Program (SNAP). SNAP is a high fidelity propagator. MALTO is a medium fidelity tool for trajectory analysis and mission design. Copernicus is suitable for both low and high fidelity analyses as a generalized spacecraft trajectory design and optimization program. Mystic is a high fidelity tool capable of N-body analysis and is the primary tool used for trajectory design, analysis, and operations of the Dawn mission. While some of the tools are export controlled, the ISPT web site does offer publicly available tools and includes instructions to request tools with distribution limitations. The ISPT systems analysis project team is conducting a series of courses for training on the ISPT supported trajectory tools. On-going tool advancements include providing MALTO and Mystic on all platforms, bug fixes, and increased capabilities.

ISPT aerocapture project released its Aerocapture Quicklook Tool, formally the multidisciplinary tool for Systems Analysis of Planetary EDL (SAPE). SAPE is a Python based multidisciplinary analysis tool for entry, decent, and landing (EDL) at Venus, Earth, Mars, Jupiter, Saturn, Uranus, Neptune, and Titan. The purpose of the SAPE tool is to provide a method of rapid assessment of aerocapture or EDL system performance, characteristics, and requirements. SAPE includes integrated analysis modules for geometry, trajectory, aerodynamics, aerothermal, thermal protection system, and structural sizing. For aerocapture and EDL system designs, systems analysis teams include systems engineers and disciplinary specific experts in flight mechanics, aerodynamics, aerothermodynamics, structural analysis, and thermal protection systems (TPS). The systems analysis process may take from several weeks to years to complete. While the role of discipline experts cannot be replaced by any tool, the integrated capabilities of SAPE can automate and streamline several parts of the analysis process significantly reducing the time and cost for preliminary assessment. SAPE continues to receive investment for assessment of Earth Entry Vehicles.

VII. Technology Infusion

The ISPT program has developed several technologies that are reaching TRL 6, and are potentially applicable for infusion into future, Flagship, New Frontiers, and Discovery mission opportunities. Three of the technologies in particular are: 1) the NASA’s Evolutionary Xenon Thruster (NEXT) ion propulsion system, 2) the Advanced Material Bi-propellant Rocket (AMBR) engine, and 3) Aerocapture. ISPT and NASA are exploring several different paths to get its technology investments infused into future NASA, DOD, or commercial missions.

NASA recognizes that it is desirable to fly new technologies that enable new scientific investigations or to enhance an investigation's science return. The Solar System Exploration (SSE) Roadmap states that NASA will strive to maximize the payoff from its technology investments, either by enabling individual missions or by enhancing classes of missions with creative solutions. Discovery, New Frontiers, and Flagship missions potentially provide opportunities to infuse advanced technologies developed by NASA. They advance NASA’s technology base
and enable a broader set of future NASA, DOD, and commercial missions.

To benefit from its technology investments, NASA provided incentives for infusion of new technological capabilities that it developed in the most recent New Frontiers and Discovery competed-mission solicitations. The incentives for NEXT, AMBR, and aerocapture were in the form of increases to the cost cap for the mission. The Decadal Survey states “these technologies continue to be of high value to a wide variety of solar system missions.” And that “NASA should continue to provide incentives for these technologies until they are demonstrated in flight.” The 2011 Planetary Decadal Survey strongly supported continuing to incentivize these technologies until they are flown. As funding and priorities allow, ISPT will strive to maintain the capabilities associated with NEXT, AMBR, and aerocapture, and ISPT will continue to look for future opportunities to infuse these technologies. Beyond the New Frontiers and Discovery opportunities, ISPT continues to seek opportunities to infuse NEXT, AMBR, aerocapture, and its other technologies into a wide range of possible future mission opportunities. ISPT will continue to help in identifying the technology development that is required to accomplish the future missions being contemplated.

### VIII. Future Plans and Conclusion

ISPT will complete current developments to TRL 6 in the near future, and as the TRL 6 developments continue, and in the future will continue to support mission infusion. Among these is the NEXT electric propulsion system. The NEXT team wraps-up PPU development and testing within the next year, but continues long-duration life testing into 2013. The NEXT system is available for all future mission opportunities. The AMBR engine reached TRL 6 in 2009, and completed the final reporting and documentation in early 2010. Finally, an aerocapture system comprised of a blunt body TPS system, the GN&C, sensors, and the supporting models achieved its technology readiness in mid-2010. Beyond completing the currently funded NEXT and aerocapture activities, future work for NEXT, AMBR, and aerocapture will be in response to future technology infusion opportunities. Regardless, if the mission requires electric propulsion, aerocapture, or a conventional chemical system, ISPT technology has the potential to provide significant mission benefits including reduced cost, risk, and trip times, while increasing the overall science capability and mission performance. Aerocapture and electric propulsion are frequently identified as enabling or enhancing technologies.

The future focus areas for ISPT are spacecraft bus and propulsion systems for sample return missions. Activity in these technology development areas increases in 2012 and 2013. The direction focuses on: 1) Planetary Ascent Vehicles; 2) multi-mission technologies for Earth Entry Vehicles required for sample return missions; and 3) electric and chemical propulsion for Earth Return Vehicles, transfer stages, and low cost Discovery-class missions. These sample return missions are inherently propulsion intensive. Several of the earlier ISPT technology areas may be involved in future sample return missions too. The mission may use Electric Propulsion for transfer to, and possibly back from, the destination. Chemical propulsion may be utilized for the ascent and descent to the surface. Aeroshells may be used for Earth re-entry and an aerocapture maneuver used to capture at the destination. Future sample return missions of interest for NASA and the science community, and those that are yet to be conceived, continue to demand propulsion systems with increasing performance and lower cost. This paper addressed how the ISPT program is starting to develop propulsion technologies for NASA’s future sample-return missions.

The planetary decadal survey identified the need for future work in propulsion, entry vehicles, and spacecraft bus and other platform technologies. ISPT will continue to work with the Planetary Science Division (PSD) to identify the propulsion technologies that will be pursued in the future. ISPT will continue to look for ways to reduce system level costs and enhance the infusion process.

### Acknowledgments

The results and findings presented here are based on work funded by the National Aeronautics and Space Administration (NASA), Science Mission Directorate (SMD). ISPT implements the project through task agreements with NASA centers, contracts with industry, and via grants with academic institutions. Implementing NASA centers include Ames Research Center (ARC), Glenn Research Center (GRC), Jet Propulsion Laboratory (JPL), Langley Research Center (LaRC), and the Marshall Space Flight Center (MSFC). There are also numerous industry partners in the development of the ISPT products. The authors acknowledge the technical achievements by the respective NASA and contractor teams and the contributions of the respective technology area project managers. In addition, we thank Linda Nero for her administrative, editorial, and clerical support of this paper.
