Extreme Ionizing-Radiation-Resistant Bacterium

Deinococcus phoenicis sp. nov. can be used as an indicator for sterilization processes in food, aerospace, medical, and pharmaceutical applications.

_NASA’s Jet Propulsion Laboratory, Pasadena, CA_

There is a growing concern that desiccation and extreme radiation-resistant, non-spore-forming microorganisms associated with spacecraft surfaces can withstand space environmental conditions and subsequent proliferation on another solar body. Such forward contamination would jeopardize future life detection or sample return technologies. The prime focus of NASA’s planetary protection efforts is the development of strategies for inactivating resistance-bearing microorganisms. Eradication techniques can be designed to target resistance-conferring microbial populations by first identifying and understanding their physiologic and biochemical capabilities that confer its elevated tolerance (as is being studied in _Deinococcus phoenicis_, as a result of this description). Furthermore, hospitals, food, and government agencies frequently use biological indicators to ensure the efficacy of a wide range of radiation-based sterilization processes. Due to their resistance to a variety of perturbations, the non-spore forming _D. phoenicis_ may be a more appropriate biological indicator than those currently in use.

The high flux of cosmic rays during space travel and onto the unshielded surface of Mars poses a significant hazard to the survival of microbial life. Thus, radiation-resistant microorganisms are of particular concern that can survive extreme radiation, desiccation, and low temperatures experienced during space travel. Spore-forming bacteria, a common inhabitant of spacecraft assembly facilities, are known to tolerate these extreme conditions. Since the Viking era, spores have been utilized to assess the degree and level of microbiological contamination on spacecraft and their associated spacecraft assembly facilities. Members of the non-spore-forming bacterial community such as _Deinococcus radiodurans_ can survive acute exposures to ionizing radiation (5 kGy), ultraviolet light (1 kJ/m²), and desiccation (years). These resistive phenotypes of _Deinococcus_ enhance the potential for transfer, and subsequent proliferation, on another solar body such as Mars and Europa. These organisms are more likely to escape planetary protection assays, which only take into account presence of spores. Hence, resistances of extreme radiation-resistant _Deinococcus_ in the cleanroom facility where spacecraft are assembled pose a serious risk for integrity of life-detection missions.

The microorganism described herein was isolated from the surfaces of the cleanroom facility in which the Phoenix Lander was assembled. The isolated bacterial strain was subjected to a comprehensive polyphasic analysis to characterize its taxonomic position. This bacterium exhibits very low 16S rRNA similarity with any other environmental isolate reported to date. Both phenotypic and phylogenetic analyses clearly indicate that this isolate belongs to the genus _Deinococcus_ and represents a novel species. The name _Deinococcus phoenicis_ was proposed after the Phoenix spacecraft, which was undergoing assembly, testing, and launch operations in the spacecraft assembly facility at the time of isolation. _D. phoenicis_ cells exhibited higher resistance to ionizing radiation (cobalt-60; 14 kGy) than the cells of the _D. radiodurans_ (5 kGy). Thus, it is in the best interest of NASA to thoroughly characterize this organism, which will further assess in determining the potential for forward contamination. Upon the completion of genetic and physiological characteristics of _D. phoenicis_, it will be added to a planetary protection database to be able to further model and predict the probability of forward contamination.
