PRSEUS Pressure Cube Test Data and Response

Andrew E. Lovejoy
Langley Research Center, Hampton, Virginia
Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA scientific and technical information (STI) program plays a key part in helping NASA maintain this important role.

The NASA STI program operates under the auspices of the Agency Chief Information Officer. It collects, organizes, provides for archiving, and disseminates NASA’s STI. The NASA STI program provides access to the NASA Aeronautics and Space Database and its public interface, the NASA Technical Report Server, thus providing one of the largest collections of aeronautical and space science STI in the world. Results are published in both non-NASA channels and by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA Programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counterpart of peer-reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.

- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.

- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.

- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.

- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA’s mission.

Specialized services also include organizing and publishing research results, distributing specialized research announcements and feeds, providing information desk and personal search support, and enabling data exchange services.

For more information about the NASA STI program, see the following:

- Access the NASA STI program home page at [http://www.sti.nasa.gov](http://www.sti.nasa.gov)

- E-mail your question to help@sti.nasa.gov

- Fax your question to the NASA STI Information Desk at 443-757-5803

- Phone the NASA STI Information Desk at 443-757-5802

- Write to: STI Information Desk NASA Center for AeroSpace Information 7115 Standard Drive Hanover, MD 21076-1320
PRSEUS Pressure Cube Test Data and Response

Andrew E. Lovejoy
Langley Research Center, Hampton, Virginia
Page 2, next to last line, the phrase that reads "Frames are spaced at 20.0 inches" should read "Frames are spaced at 24.0 inches".

Issue Date: January 2014

xiv
Introduction

In an effort to increase the fuel efficiency of commercial aircraft, numerous configuration concepts have been developed. One such concept is the hybrid wing body (HWB) shown in Fig. 1, which was the initial focus of NASA’s Environmentally Responsible Aviation (ERA) Program. The HWB design combines features of a flying wing with features of conventional transport aircraft, a configuration that has the advantage of simultaneously increasing both fuel efficiency and payload. Early in the formulation of the HWB concept, it was realized that conventional structural configurations of the time limited the potential design space for lightweight primary structure. Therefore, the conventional pressurized cabin structure was abandoned with the expectation that future structural concepts would be developed that were capable of sustaining the anticipated HWB loads. As a result, initial HWB research focused on the aerodynamic, stability and control issues (flying characteristics), which included wind tunnel tests at NASA Langley Research Center (LaRC). While later studies have continued to address HWB flying characteristics, including noise and propulsion issues, recent years have seen an increased focus on the structural performance of the HWB. The key structural challenge of a HWB airframe is the ability to create a cost and weight efficient, non-circular, pressurized shell. Conventional round fuselage sections react cabin pressure by hoop tension. However, the structural configuration of the HWB subjects the majority of the structural panels to bi-axial, in-plane loads in addition to the internal cabin pressure. Therefore, the design and sizing of these nearly flat pressurized panels (identified by the shaded region in Fig. 3) requires more thorough examination and analysis than conventional transport aircraft components that have traditional and less complex load paths. To address this issue, while keeping HWB structural weights low, extensive use of advanced composite materials is made that results in architectures that are appreciably lighter than comparable aluminum designs. This report presents the test data and preliminary conclusions for a pressurized cube test article that is part of the building block approach used for HWB development.

PRSEUS concept

Several sizing and optimization studies have been conducted on HWB-like structures. Of particular importance is the response of the non-circular HWB structure subjected to internal pressure, where double bending curvature (center and edges of the panel bending in opposite directions) is experienced by the pressurized panel that results in large local stresses that drive the panel design. This phenomenon is discussed in Refs. 3 and 7, and emphasizes the potential inefficiency of a uniform panel design unless the structural concept is highly efficient. One structural concept that shows great promise for application to a HWB center section is the Pultruded Rod Stitched Efficient Unitized Structure (PRSEUS) developed by the Boeing Company. PRSEUS is an integral structural concept whereby skins, frames, stringers and tear straps are all stitched together, then infused and cured in an out-of-autoclave process. The concept has evolved out of stitching technology development from several NASA-Boeing and AFRL-Boeing programs beginning in the 1990’s. An expanded view of a PRSEUS stiffener intersection is shown in Fig. 4. The key to the PRSEUS concept is the pre-cured, pultruded rod that is contained within the stringer wrap plies and which passes through the frames, providing an uninterrupted load path. At the same time, the full depth frame stiffener is also continuous, except for the key-hole through which the stringer passes, providing an uninterrupted load path in the direction perpendicular to the stringer. These efficient structural stiffening members provide the majority of the panel stiffness, permitting the use of minimum skin thickness for many applications.

PRSEUS uses dry warp-knit fabric materials stitched together to create a preform of the full structural panel, so that all materials can be co-cured with minimal use of inner moldline tooling. Skins, flanges, and webs comprise layers of graphite material forms that are pre-knitted into multi-ply stacks of Hercules,
Inc. AS4 fibers. Multiple stacks of the warp-knit material are used to build up the desired part thickness and configuration. In order to maintain the panel geometry during fabrication, frames and stringers are placed in a stitching tool, and then the skin stack(s) are placed in the stitching tool to prepare for stitching of the assembly. The assembly is stitched together using Vectran thread, then the assembly is moved to a curing tool for resin infusion and consolidation in an oven using Boeing’s Controlled Atmospheric Pressure Resin Infusion (CAPRI) process. Since the stiffener flanges are stitched to the skin, no mechanical fasteners are used for joining the assembly structural elements. Stringers, the stiffeners running in the HWB axial direction, consist of AS4 carbon fiber webs that overwrap a bulb-shaped, pe-cured rod of unidirectional, pultruded carbon fiber at the top of the web. Frame stiffeners are oriented along the spanwise direction, and are foam filled blades. The pultruded rods currently used in PRSEUS construction are Toray unidirectional T800 fiber with a 3900-2B resin, and currently, the frames are filled with Rohacell foam. The warp-knit stacks that are currently used in the PRSEUS skin and stiffeners make use of a (44/44/12) fiber architecture, in terms of an area weight percentage of (0/±45/90) degree plies, with a nominal stack thickness of 0.052 inches. The resin system currently used to infuse the PRSEUS assembly is HexFlow VRM 34. Lastly, in the current HWB design, the 44% 0-degree orientation of the fuselage skin is parallel to the frames in the aircraft span-wise direction.

**Building Block Approach**

Under the HWB structural development program, a building block approach has been used to design, analyze, build and test structural components as depicted in Fig. 5. The first pressurized PRSEUS structure was a flat panel, which is identified as the internal pressure box in the figure. This pressure panel fit into the sub-component testing portion of the Technology Readiness Level (TRL) 4 development effort. It was designed, analyzed and fabricated by Boeing, and it was tested at NASA LaRC. The pressure panel demonstrated the pressure loading capability of minimum gauge PRSEUS panels, where the panel withstood the 2P overpressure load both without and with barely visible impact damage (BVID) imparted on a stringer, with initial failure at a pressure of 28.44 psi with BVID present. As a next step in the building block approach, the behavior of a cube assembly made from integral PRSEUS panels that is subjected to pressure loading was examined. This test article is identified in Fig. 5 as the Pressure Cube, and it is the focus of this report. The pressure cube is an intermediate test article in the building block plan meant to reduce risk in the TRL 5 large-scale test, shown as the last step in the figure, by demonstrating PRSEUS assembly joint concepts under 2P loading. Again, this activity is a joint effort between NASA and Boeing, where Boeing completed design, analysis, manufacturing, and assembly of the test article, and NASA conducted pressure testing at LaRC’s Combined Loads Test Systems (COLTS) facility, and provided analysis and post-test correlation.

**Pressure Cube Design**

The PRSEUS pressure cube, shown in Fig. 6, consists of six composite PRSEUS panels assembled together using aluminum fittings and a new stitched integral cap joint concept. Using the HWB as the baseline (Fig. 1), the pressure cube is designed such that it represents a region of the HWB pressurized fuselage section (Fig. 4) incorporating the crown skin, two side ribs, two side bulkheads, and a pressurized floor section as shown in Fig. 6. The crown panel is representative of the upper cover panel of the baseline aircraft in the pressure cabin region. The sides of the pressure cube are two pairs of opposing panels, arranged symmetrically, that represent rib and bulkhead panel regions. The rib and bulkhead panels are representative of the outer cabin pressure-carrying ribs and the rear pressure bulkhead of the baseline aircraft, respectively. With the exception of edge build-ups and integral caps described subsequently, all panels used in the pressure cube have the same design as the previously tested pressure panel. Frames are spaced at 20.0 inches, stringers are spaced at 6.0 inches, and with the exception of the floor, the skin is minimum gauge with a nominal thickness of 0.052 inches. The floor panel is not strictly
representative of the baseline aircraft because of the required access door and instrumentation pass-through. However, for convenience, the floor was designed to use available panel tooling, so that the stiffener spacing is identical to the remainder of the cube, but the skin thickness is significantly greater, and pad-ups have been added around the cutouts. Stringer and frame cross-sections are shown in Fig. 7, with nominal stringer and frame heights, measured from the outer mold line, of 1.49 and 6.0 inches, respectively.

Stitched T-shaped integral caps are manufactured into the panels to reduce the complexity and number of metallic fittings required to assemble the panels together. The integral cap joint design is the primary focus of the pressure cube risk reduction test article. As the first test specimen where PRSEUS panels have been joined together to create 90-degree corners, the primary purpose of the pressure cube test was to verify that the joint concept could hold the adjusted 2P load case that would be scaled up to account for the subscale cube dimensions. Integral cap members are incorporated around all four edges of the crown panel to provide a means of attaching the cube side panels (Fig. 6). The rib panels incorporate integral flanges to provide a means of attachment to the bulkhead panels. The bulkhead panels have only one cap at the lower end where they interface with the floor panel. A key feature of the pressure cube design is that there are few fasteners protruding through the outer mold line of the panel that is exposed to the airstream.

**Pressure Cube Testing**

The pressure cube was tested in the NASA LaRC COLTS facility in August of 2011. Preliminary tests were completed to perform instrumentation checks, followed by tests of the pristine pressure cube, and then the pressure cube was impacted with BVID and pressurized to failure. This section describes the test set-up and test procedure, and concludes by presenting the test data for all applied pressure loadings.

**Test Set-up**

The test set-up for the pressure cube is shown in Fig. 8. The crown, one rib, one bulkhead and the floor were painted with flat white-gray paint on the outer mold line (OML). The remaining rib and bulkhead were painted with a white speckle pattern to be used with a video digital image correlation system, VIC-3D (hereafter referred to as VIC). The pressure cube was instrumented with 11 direct current displacement transducers (DCDTs) and 168 strain gages. The locations of all DCDTs and strain gages are described in Tables 1 and 2, respectively. For the strain gage designations, the terminology is as follows: A indicates OML, B indicates inner mold line (IML), S indicates skin, W indicates web and F indicates flange. The locations of the DCDTs with respect to the cube are shown in Fig. 9, where the cube has been unfolded, with the floor removed for clarity. In the figure, the relationship between the panels on which the VIC systems were used and the remaining panels is shown, with the arrows indicating mating edges of the cube. Similarly, the general locations of the strain gages for each side of the cube are shown in Figures 10 – 15. In the figures, each edge of the panel is identified by the mating panel to which that edge is attached (e.g., an edge labeled as “crown” indicates that edge is attached to the crown panel). VIC was used to monitor displacements and strains on the speckled rib and bulkhead panels. Two VIC systems were used for global measurements, one for the rib and one for the bulkhead. A third VIC system was added in the final load-to-failure test to monitor a local region on the rib in the vicinity of BVID. Additionally, the interior of the pressure cube was monitored using video cameras with light-emitting diode (LED) lighting, and several cameras provided video monitoring of the exterior of the pressure cube. Lastly, acoustic emission (AE) sensors were installed on all of the panels except for the floor. Several of the AE sensors can be seen in Fig. 8, and their pattern and numbering is shown in Fig. 16. Full details associated with the AE portion of the testing can be found in Ref. 19.
Due to the danger involved with pressurized tests, the cube was tested in the COLTS pressure chamber. This chamber is an enclosed volume that can contain the explosive failure of a pressurized test article up to the size of a 45-foot long fuselage section. Output signals from DCDTs, strain gages, VIC computers and AE sensors on were monitored in the COLTS control room.

Test Procedure

The pressure cube was subjected to several pressure loads to various levels in a pristine condition, and pressure loaded to failure with BVID imparted to the exterior of the cube at a rib integral cap web location. Design pressures for the cube are designated as 1P, which represents the normal operating pressure of 9.2 psi, and 2P, which represents the 18.4 psi maximum overpressure condition. In the pristine condition, two check-out tests were conducted with the pressure ramped up to 4.6 psi (0.5P). These check-out tests were used to verify proper operation of all data acquisition systems and the pressure control system. The pristine cube was then pressurized up to 1P and then unpressurized. During the 1P testing, vibration surveys were performed to provide data used to validate finite element models to enable accurate prediction of pressurized PRSEUS panel dynamics. The vibration surveys were made at zero pressure and 1P, and at 6 steady-state pressure holds through the loading up to 1P. The final pristine cube test increased the pressure up to 20.15 psi (2.2P) prior to being unpressurized. The purpose of the 2.2P load is to ensure that no failure will occur for the overpressure condition, but with an additional margin of 10% included. At the conclusion of the pristine cube tests, the cube was examined using ultrasonic NDI and the BVID was introduced. The cube was turned on its side, NDI was performed, then BVID was imparted, using a drop weight impactor, to the speckled rib integral cap web that attached the rib to the speckled bulkhead, as shown in Figure 17. The location of the BVID with respect to the integral cap web is shown in Figure 18, and its location on the cube is shown in Figure 19. The BVID was imparted with an impact energy of 100 ft-lbs using a 1-inch spherical impactor. Figure 20 shows the impact location surface before and after introducing the BVID. Additional NDI was performed in the vicinity of the BVID with the cube on its side prior to being rotated back to the test position and reinstalling DCDTs. The pressure cube was then pressurized until catastrophic failure occurred. NDI was performed on what remained of the cube after the catastrophic failure.

Test Data

As described in the test set-up section, data was collected on the pressure cube using DCDTs, strain gages and VIC. Data was collected for all test loads; the two 0.5P check-out tests, the 1P test, the 2.2P test and the test to failure. Plots of all DCDT and strain gage test data for all five of the test loads is provided for reference in Appendices A through E. The two check-out tests were uneventful, as was expected since the load level was low. Data for the two check-out tests is provided in Appendices A and B. The third loading took the pressure cube to 1P, and the maximum center-of-panel displacement measured by the DCDTs for the crown, rib and bulkhead were 0.042, 0.0098 and 0.19 inches, respectively. The only strain gage that showed other than smooth response was SG95AW, as shown in Figure 21. As described in Table 2, this gage is above a keyhole, and this slope discontinuity could be attributed to cracking or failure of the resin that collects between the stringer and integral cap web during infusion. The stringers are expected to pass through keyholes without any connection, but resin collects in the keyhole region providing a weak connection between the stringer and structure in which the keyhole exists (i.e. frame, integral cap). Therefore, testing showed no unexpected response up to 1P. Complete data for the 1P loading condition is presented in Appendix C.

The cube was then loaded to 2.2P. No catastrophic failure or visible damage resulted from the 2.2P loading. However, test data indicates that nonvisible damage did occur. DCDT6 showed significant slope discontinuities in the displacement-load relationship at about 16 and 19 psi, as shown in Figure 22. The
strain gage results in the vicinity of DCDT6 show slope discontinuities at the same pressure levels, as shown in Figures 23-25. Also, similar behavior is seen at crown and rib gages in the mirrored locations, as shown in Figures 26-28. Numerous other gages showed mildly nonlinear behavior and minor slope discontinuities in strain level, but they were not as severe as those shown in the figures. The ultrasonic NDI performed after the completion of this load level (see Ref. 21) indicated that delaminations developed in the vicinity of the crown integral caps attached to the ribs, as shown in Figure 29, which is consistent with the DCDT and strain gage data that was presented. Therefore, no visible damage was observed, but there was internal, nonvisible damage after the 2.2P load. Complete data for the 2.2P loading condition is presented in Appendix D.

Lastly, the pressure cube was subjected to BVID and loaded to catastrophic failure. Throughout the loading, many indications of local damage were observed by the DCDTs and strain gages, but no visible damage was observed, and catastrophic failure did not occur until 48 psi. Complete data for the loading to catastrophic failure is presented in Appendix E, and results of interest are presented here. Displacement plots for selected DCDTs are shown in Figures 30-33, and are for the panel center displacements and DCDT6 that was located at one of the crown delaminations. The VIC-measured displacements at several pressure levels are shown in Figures 34-39 for the rib and bulkhead. VIC-measured displacements just prior to catastrophic failure are shown in Figures 40 and 41 for the rib and bulkhead, respectively, with a close-up of the BVID region shown in Figure 42. No effect of the BVID presence can be seen in Figure 42. A large number of strain gages exhibited nonlinear behavior or small slope discontinuities in the strain level, but the majority of these recorded very small strain levels, in many cases on the order of a few hundred microstrain. The maximum strains observed were on the bulkhead frame in the vicinity of a keyhole and on the cap, as shown in Figures 43-44. In the vicinity of the keyhole, the strain exhibited instantaneous slope discontinuity, increasing from -4,000 με to -12,000 με at 45.7 psi for SG83BW, and from -5,000 με to -12,000 με from 47 to 48 psi for SG75BW. However, at the keyhole, local failures would be expected due to the stress concentration, but these local failures do not necessarily lead to catastrophic failure. The maximum strains in the frame caps were approximately -10,000 με as seen in Figures 45-46. Figures 47-50 show the response of the strain gages in the vicinity of the two delamination locations on the crown panel, where continued delamination growth can be identified as indicated by the slope discontinuities in strain recorded by the gages. Nonlinear behavior of the skin is demonstrated by the strain gage plots shown in Figures 51 and 52, for gages located near the center of the gray bulkhead. However, the strains for these gages are well within the specified allowable values, as are almost all of the strains recorded by the gages. Finally, the pressure cube after failure is shown in Figure 53. In addition to the composite failure, failure in the aluminum connection between the crown panel and speckled rib frames was found, as shown in Figure 54. Frame buckling of the speckled rib frame attached to the failed aluminum connection is observed as shown in Figure 55.

**Discussion and Conclusions**

This document presents the complete displacement and strain gage data for the PRSEUS pressure cube test conducted at the NASA LaRC COLTS test facility. For the two checkout loading conditions, up to 0.5P pressure, no abnormal behavior of the cube was observed. In the third loading condition, which was pressurized up to 1P, normal and smooth response was observed for all displacements and strains except for strain gage SG95AW, where several slope discontinuities in strain were seen, but strain levels remained less than 720 microstrain. The cube was presurized a fourth time up to a load level of 2.2P. During this fourth loading, displacement and strain slope discontinuities were observed. Subsequent NDE identified delaminations in the vicinity of the crown integral caps that connect the crown to the ribs. The final loading was to catastrophic failure after BVID was introduced into the integral cap attaching the speckled rib to the speckled bulkhead. Numerous nonlinear strain responses, including slope discontinuities in strain, were observed. However, the majority of the strains recorded remained within
the allowable strain levels. Also, no effect of the BVID presence was observed in the VIC data or strain gage data. The initial most likely final failure sequence is speculative due to the fact that the failure occurred instantaneously and there were no indications by the instrumentation from which to draw clear conclusions. However, catastrophic first failure of the frame fitting is supported by the analysis, test data and observed failure modes. A possible future effort could entail examination of the data presented herein in conjunction with the AE and NDE data presented in References 19 and 21, respectively, to provide better insight into the failure sequence of the pressure cube.

Figures

Figure 1. Typical HWB aircraft concept.

Characteristics
- Wing Area \((\text{trap})\) = 4,003 ft\(^2\)
- Wing Span = 185.7 ft
- Wing Sweep = 35.5°
- Cruise = .85 Mach
- Range = 7,500 nm

Weights
- MTOW = 408,700 lbs
- MLW = 289,100 lbs
- MZFW = 273,100 lbs

Payload
- 44,310 lb Capability

Figure 2. HWB conceptual vehicle and loading patterns.
Figure 3. Typical pressurized portion of a HWB aircraft concept.

Figure 4. PRSEUS stiffener intersection expanded view.
Phase I: Element-level Testing:
- Combined Load Environment:
  - Spanwise Axial
  - Chordwise Axial
  - Internal Pressure
- 2.5-g Wing bending
- 9-g Fwd (Engines)
- Cabin Pressure (1P and 2P)

Phase I and II: Analytical Trades Studies:
- Stringer and Frame Directions
- Static Axially Loaded (Fx and Fy)
- Analytical Predictions
- Test Loads
- Panel Geometry

Phase II: Subcomponent Testing:
- Stringer and Frame Directions
- Static Axially Loaded (Fx and Fy)
- Pressure Box (Fz)
- Analytical Predictions

TRL 4 - Validation by Test
- Flat Comp Panels
- Min Gauge
- Internal Pressure Box

TRL 5 - Testing in Relevant Environment
- Pressure and Axial Loads (Fx and Fz)
- Accurate BWB Representation
- Double Deck Pressure Test
- Risk Reduction Test Article
- COLTS Test Specimen

Phase III: True Combined Loads Testing:
- Pressure Cube Design (48-in. wide)
- Pressure Cube (52-in. x 48-in. x 56-in Tall)

Pressure cube loads will be scaled up to demonstrate multi-bay box capability

Figure 5. HWB structural development building block approach.

**14. ABSTRACT**

NASA’s Environmentally Responsible Aviation (ERA) Program is examining the hybrid wing body (HWB) aircraft, among others, in an effort to increase the fuel efficiency of commercial aircraft. The HWB design combines features of a flying wing with features of conventional transport aircraft, and has the advantage of simultaneously increasing both fuel efficiency and payload. Recent years have seen an increased focus on the structural performance of the HWB. The key structural challenge of a HWB airframe is the ability to create a cost and weight efficient, non-circular, pressurized shell. Conventional round fuselage sections react cabin pressure by hoop tension. However, the structural configuration of the HWB subjects the majority of the structural panels to bi-axial, in-plane loads in addition to the internal cabin pressure, which requires more thorough examination and analysis than conventional transport aircraft components having traditional and less complex load paths. To address this issue, while keeping structural weights low, extensive use of advanced composite materials is made. This report presents the test data and preliminary conclusions for a pressurized cube test article that utilizes Boeing’s Pultruded Rod Stitched Efficient Unitized Structure (PRSEUS), and which is part of the building block approach used for HWB development.

**15. SUBJECT TERMS**

PRSEUS; carbon-epoxy; composite; graphite; hybrid wing body; internal pressure; stitching
