NASA STI Program . . . in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA scientific and technical information (STI) program plays a key part in helping NASA maintain this important role.

The NASA STI program operates under the auspices of the Agency Chief Information Officer. It collects, organizes, provides for archiving, and disseminates NASA’s STI. The NASA STI program provides access to the NASA Aeronautics and Space Database and its public interface, the NASA Technical Report Server, thus providing one of the largest collections of aeronautical and space science STI in the world. Results are published in both non-NASA channels and by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA Programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counterpart of peer-reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.

- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.

- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.

- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.

- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA’s mission.

Specialized services also include organizing and publishing research results, distributing specialized research announcements and feeds, providing information desk and personal search support, and enabling data exchange services.

For more information about the NASA STI program, see the following:

- Access the NASA STI program home page at [http://www.sti.nasa.gov](http://www.sti.nasa.gov)

- E-mail your question to [help@sti.nasa.gov](mailto:help@sti.nasa.gov)

- Fax your question to the NASA STI Information Desk at 443-757-5803

- Phone the NASA STI Information Desk at 443-757-5802

Abstract

Combining symbolic techniques such as: (i) SMT solving, (ii) rewriting modulo theories, and (iii) model checking can enable the analysis of infinite-state systems outside the scope of each such technique. This paper proposes rewriting modulo SMT as a new technique combining the powers of (i)-(iii) and ideally suited to model and analyze infinite-state open systems; that is, systems that interact with a non-deterministic environment. Such systems exhibit both internal non-determinism due to the system, and external non-determinism due to the environment. They are not amenable to finite-state model checking analysis because they typically are infinite-state. By being reducible to standard rewriting using reflective techniques, rewriting modulo SMT can both naturally model and analyze open systems without requiring any changes to rewriting-based reachability analysis techniques for closed systems. This is illustrated by the analysis of a real-time system beyond the scope of timed automata methods.
1 Introduction

Symbolic techniques that represent possibly infinite sets of states by symbolic constraints have become essential to make formal verification — using model checking, theorem proving, or combining features from both — much more scalable. They provide high levels of automation when verifying various kinds of infinite-state systems. Such techniques have been rigorously developed, adopted in many systems, and proved highly successful. They include: (i) SAT solving and other decision procedures, and their combination into Satisfiability Modulo Theories (SMT) solvers; (ii) rewriting- and unification-based techniques, including rewriting modulo theories and narrowing modulo theories; and (iii) symbolic model checking techniques.

A key open research issue limiting the applicability of current symbolic techniques is lack of, or limited support for, extensibility. That is, although certain classes of systems can be formalized in ways that enable the application of specific symbolic analysis techniques, many other systems of interest (Section 6 provides an example) fall outside the scope of some existing symbolic techniques. In such cases one would like to extend and combine the power of symbolic techniques to analyze the given system.

Certainly, some techniques to combine methods or procedures provide useful ways of broadening the scope of methods and tools. For example: (i) combinations of decision procedures, e.g., [26, 27]; and of unification algorithms, e.g., [5, 10]; (ii) combinations of theorem provers with decision procedures, e.g., [1, 9, 31]; and (iii) integration of SMT solvers in model checkers, e.g., [3, 17, 25, 34, 36]. However, it seems fair to say that at present there is a lack of general extensibility techniques for symbolic analysis that can simultaneously combine the power of SMT solving, rewriting- and narrowing-based analysis, and symbolic model checking to analyze systems beyond the scope of each separate analysis technique.

The main goal of the present work is to propose a new symbolic technique that seamlessly combines the powers of rewriting modulo theories, SMT solving, and model checking. For brevity, this technique is called rewriting modulo SMT, although it could more precisely be called “rewriting modulo SMT+B,” where B is any equational theory having a matching algorithm. It complements, and has similarities with, another symbolic technique combining narrowing modulo theories and model checking, namely, narrowing-based reachability analysis [24] and its extension to symbolic LTL model checking [7].

Rewriting modulo SMT can be usefully applied to increase the power of equational reasoning, but its full power (including its model checking capabilities) is best exploited when applied to concurrent open systems. The key point is that deterministic systems can be naturally specified by equational theories, but specification of concurrent, non-deterministic systems requires rewrite theories [21], that is, triples \( R = (\Sigma, E, R) \) with \((\Sigma, E)\) an equational theory describing system states as elements of the initial algebra \( T_{\Sigma/E} \), and \( R \) rewrite rules describing the system’s local concurrent transitions. Although extensive experience and many tools exist to specify and analyze concurrent systems in this way (see the survey [23]), the specification of concurrent open systems remains quite challenging. However, as explained below, specification and analysis of open systems becomes easy and unproblematic with
rewriting modulo SMT.

An open system is a concurrent system that interacts with an external, non-deterministic environment. When such a system is specified by a rewrite theory \( R = (\Sigma, E, R) \), it has two sources of non-determinism, one internal and the other external. Internal non-determinism comes from the fact that in a given system state different instances of rules in \( R \) may be enabled, and the local transitions thus enabled may lead to completely different states. What is peculiar about an open system is that it also has external, and often infinitely-branching, non-determinism due to the environment. That is, the state of an open system must include the state changes due to the environment. Technically, this means that, while a system transition in a closed system can be described by a rewrite rule \( t \rightarrow t' \) with \( \text{vars}(t') \subseteq \text{vars}(t) \), a transition in an open system is instead modeled by a rule of the form \( t(x) \rightarrow t'(x, y) \), where \( y \) represents fresh new variables. Therefore, a substitution for the variables \( x \) decomposes into two substitutions, one, say \( \theta \), for the variables \( x \) under the control of the system, and another, say \( \rho \), for the variables \( y \) under the control of the environment. In rewriting modulo SMT such open systems are described by conditional rewrite rules of the form \( t(x) \rightarrow t'(x, y) \) if \( \phi \), where \( \phi \) is a constraint solvable by an SMT solver. This constraint \( \phi \) may still allow the environment to choose an infinite number of substitutions \( \rho \) for the variables \( y \), but can exclude choices that the environment will never make.

The non-trivial challenges of modeling and analyzing open systems can now be better explained. They include: (1) the enormous and possibly infinitary non-determinism due to the environment, which typically renders finite-state model checking impossible or unfeasible; (2) the impossibility of executing the rewrite theory \( R = (\Sigma, E, R) \) in the standard sense, due to the non-deterministic choice of \( \rho \); and (3) the in general undecidable challenge of checking the rule’s condition \( \phi \), since without knowing \( \rho \), the condition \( \phi \theta \) is non-ground, so that its \( E \)-satisfiability may be undecidable, even for \( E \) confluent and terminating. As further explained in the paper, challenges (1)–(3) are all met successfully by rewriting modulo SMT because: (1) states are represented not as concrete states (i.e., ground terms) but as symbolic constrained terms \( \langle t; \varphi \rangle \) with \( t \) a term with variables ranging in the domain(s) handled by the SMT solver and \( \varphi \) an SMT-solvable formula, so that the choice of \( \rho \) is avoided; (2) rewriting modulo SMT can symbolically rewrite such pairs \( \langle t; \varphi \rangle \) (describing possibly infinite sets of concrete states) to other pairs \( \langle t'; \varphi' \rangle \); and (3) decidability of \( \phi \theta \) (more precisely of \( \varphi \land \phi \theta \)) can be settled by invoking an SMT solver.

How rewriting modulo SMT is seamlessly integrated with a symbolic style of model checking for infinite-state systems, thus combining the power of rewriting, SMT solving, and model checking, is also worth explaining. The essential point (further expanded in Section 5) is that, by exploiting the fact that rewriting logic is reflective [14], rewriting modulo SMT can be reduced to standard rewriting. Specifically, this means that all the techniques, algorithms, and tools available for model checking closed systems specified as rewrite theories, such as Maude’s search-based reachability analysis [13], become directly available to perform symbolic reachability analysis on systems that are now infinite-state. This is illustrated by the formal analysis of an infinite-state real-time system outside the scope of timed-automata.
the identity only for a finite subset of preregular responding order-sorted \( \Sigma \)-term algebras. All order-sorted signatures are assumed the domain of \( \theta \). The function symbols in \( F \) can be subsort-overloaded and satisfy the condition that, for \((w,s),(w',s') \) \( \in S^* \times S \), if \( f \in F_{w,s} \cap F_{w',s'} \), then \( w\equiv_S w' \) implies \( s\equiv_S s' \). A top sort in \( \Sigma \) is a sort \( s \in S \) such that if \( s' \in S \) and \( s \equiv_S s' \), then \( s' \leq s \). For any sort \( s \in S \), the expression \([s]\) denotes the connected component of \( s \), that is, \([s] = [s]_{\equiv_S} \).

The variables \( X \) are an \( S \)-indexed family \( X = \{X_s\}_{s \in S} \) of disjoint variable sets with each \( X_s \) countably infinite. The set of terms of sort \( s \) is denoted \( T_{\Sigma}(X)_s \) and the set of ground terms of sort \( s \) is denoted \( T_{\Sigma,s}(X) \) and \( T_{\Sigma} \) denote the corresponding order-sorted \( \Sigma \)-term algebras. All order-sorted signatures are assumed preregular [18], i.e., each \( \Sigma \)-term has a least sort \( l(s) \in S \) s.t. \( t \in T_{\Sigma}(X)_{l(s)} \). For \( S' \subseteq S \), a term is called \( S' \)-linear if no variable with sort in \( S' \) occurs in it twice. The set of variables of \( t \) is written \( \text{vars}(t) \).

A substitution is an \( S \)-indexed mapping \( \theta : X \rightarrow T_{\Sigma}(X) \) that is different from the identity only for a finite subset of \( X \). The identity substitution is denoted by \( id \) and \( \theta|_Y \), denotes the restriction of \( \theta \) to a family of variables \( Y \subseteq X \). \( \text{dom}(\theta) \) denotes the domain of \( \theta \), i.e., the subfamily of \( X \) for which \( \theta(x) \neq x \), and \( \text{ran}(\theta) \) denotes the family of variables introduced by \( \theta(x) \), for \( x \in \text{dom}(\theta) \). Substitutions extend homomorphically to terms in the natural way. A substitution \( \theta \) is called ground iff \( \text{ran}(\theta) = \emptyset \). The application of a substitution \( \theta \) to a term \( t \) is denoted by \( t\theta \) and the composition of two substitutions \( \theta_1 \) and \( \theta_2 \) is denoted by \( \theta_1 \theta_2 \). A context \( C \) is a \( \lambda \)-term of the form \( C = \lambda x_1, \ldots, x_n.c \) with \( c \in T_{\Sigma}(X) \) and \( \{x_1, \ldots, x_n\} \subseteq \text{vars}(c) \); it can be viewed as a \( n \)-ary function \( C(t_1, \ldots, t_n) = c\theta \), where \( \theta(x_i) = t_i \) for \( 1 \leq i \leq n \) and \( \theta(x) = x \) otherwise.

A \( \Sigma \)-equation is an unoriented pair \( t = u \) with \( t \in T_{\Sigma}(X)_{s_t}, u \in T_{\Sigma}(X)_{s_u} \), and \( s_t \equiv_S s_u \). A conditional \( \Sigma \)-equation is a triple \( t = u \) if \( \gamma \), with \( t = u \) a \( \Sigma \)-equation and \( \gamma \) a finite conjunction of \( \Sigma \)-equations; it is called unconditional if \( \gamma \) is the empty conjunction. An equational theory is a tuple \((\Sigma,E)\), with \( \Sigma \) an order-sorted signature and \( E \) a finite collection of (possibly conditional) \( \Sigma \)-equations. We assume throughout that \( T_{\Sigma,s} \neq \emptyset \) for each \( s \in S \), because this affords a simpler deduction system. An equational theory \( E = (\Sigma,E) \) induces the congruence relation \( =_E \) on \( T_{\Sigma}(X) \) defined for \( t,u \in T_{\Sigma}(X) \) by \( t =_E u \) iff \( E \vdash t = u \) by the deduction

2 Preliminaries

We recall notation on terms, term algebras, and equational theories as in [6,18].

An \( \text{order-sorted signature} \) \( \Sigma \) is a tuple \( \Sigma = (S,\leq,F) \) with a finite poset of sorts \((S,\leq)\) and set of function symbols \( F \). The binary relation \( \equiv_S \) denotes the equivalence relation generated by \( \leq \) on \( S \) and its point-wise extension to strings in \( S^* \). The function symbols in \( F \) can be subsort-overloaded and satisfy the condition that, for \((w,s),(w',s') \) \( \in S^* \times S \), if \( f \in F_{w,s} \cap F_{w',s'} \), then \( w\equiv_S w' \) implies \( s\equiv_S s' \). A top sort in \( \Sigma \) is a sort \( s \in S \) such that if \( s' \in S \) and \( s \equiv_S s' \), then \( s' \leq s \). For any sort \( s \in S \), the expression \([s]\) denotes the connected component of \( s \), that is, \([s] = [s]_{\equiv_S} \).

The variables \( X \) are an \( S \)-indexed family \( X = \{X_s\}_{s \in S} \) of disjoint variable sets with each \( X_s \) countably infinite. The set of terms of sort \( s \) is denoted \( T_{\Sigma}(X)_s \) and the set of ground terms of sort \( s \) is denoted \( T_{\Sigma,s}(X) \) and \( T_{\Sigma} \) denote the corresponding order-sorted \( \Sigma \)-term algebras. All order-sorted signatures are assumed preregular [18], i.e., each \( \Sigma \)-term has a least sort \( l(s) \in S \) s.t. \( t \in T_{\Sigma}(X)_{l(s)} \). For \( S' \subseteq S \), a term is called \( S' \)-linear if no variable with sort in \( S' \) occurs in it twice. The set of variables of \( t \) is written \( \text{vars}(t) \).

A substitution is an \( S \)-indexed mapping \( \theta : X \rightarrow T_{\Sigma}(X) \) that is different from the identity only for a finite subset of \( X \). The identity substitution is denoted by \( id \) and \( \theta|_Y \) denotes the restriction of \( \theta \) to a family of variables \( Y \subseteq X \). \( \text{dom}(\theta) \) denotes the domain of \( \theta \), i.e., the subfamily of \( X \) for which \( \theta(x) \neq x \), and \( \text{ran}(\theta) \) denotes the family of variables introduced by \( \theta(x) \), for \( x \in \text{dom}(\theta) \). Substitutions extend homomorphically to terms in the natural way. A substitution \( \theta \) is called ground iff \( \text{ran}(\theta) = \emptyset \). The application of a substitution \( \theta \) to a term \( t \) is denoted by \( t\theta \) and the composition of two substitutions \( \theta_1 \) and \( \theta_2 \) is denoted by \( \theta_1 \theta_2 \). A context \( C \) is a \( \lambda \)-term of the form \( C = \lambda x_1, \ldots, x_n.c \) with \( c \in T_{\Sigma}(X) \) and \( \{x_1, \ldots, x_n\} \subseteq \text{vars}(c) \); it can be viewed as a \( n \)-ary function \( C(t_1, \ldots, t_n) = c\theta \), where \( \theta(x_i) = t_i \) for \( 1 \leq i \leq n \) and \( \theta(x) = x \) otherwise.

A \( \Sigma \)-equation is an unoriented pair \( t = u \) with \( t \in T_{\Sigma}(X)_{s_t}, u \in T_{\Sigma}(X)_{s_u} \), and \( s_t \equiv_S s_u \). A conditional \( \Sigma \)-equation is a triple \( t = u \) if \( \gamma \), with \( t = u \) a \( \Sigma \)-equation and \( \gamma \) a finite conjunction of \( \Sigma \)-equations; it is called unconditional if \( \gamma \) is the empty conjunction. An equational theory is a tuple \((\Sigma,E)\), with \( \Sigma \) an order-sorted signature and \( E \) a finite collection of (possibly conditional) \( \Sigma \)-equations. We assume throughout that \( T_{\Sigma,s} \neq \emptyset \) for each \( s \in S \), because this affords a simpler deduction system. An equational theory \( E = (\Sigma,E) \) induces the congruence relation \( =_E \) on \( T_{\Sigma}(X) \) defined for \( t,u \in T_{\Sigma}(X) \) by \( t =_E u \) iff \( E \vdash t = u \) by the deduction
rules for order-sorted equational logic in [22]. Similarly, \(=^1_\mathcal{E}\) denotes provable \(\mathcal{E}\)-equality in one step of deduction. The \(\mathcal{E}\)-subsumption ordering \(\ll_\mathcal{E}\) is the binary relation on \(T_\Sigma(X)\) defined for any \(t, u \in T_\Sigma(X)\) by \(t \ll_\mathcal{E} u\) if there is a substitution \(\theta : X \rightarrow T_\Sigma(X)\) such that \(t =_\mathcal{E} u\theta\). A set of equations \(E\) is called collapse-free for a subset of sorts \(S' \subseteq S\) iff for any \(t = u \in E\) and any substitution \(\theta : X \rightarrow T_\Sigma(X)\) neither \(t\theta\) nor \(u\theta\) are a variable for some sort \(s \in S'\). \(T_\mathcal{E}(X)\) and \(T_\mathcal{E}\) (also written \(T_{\Sigma/E}(X)\) and \(T_{\Sigma/E}\)) denote the quotient algebras induced by \(=_{\mathcal{E}}\) on the term algebras \(T_\Sigma(X)\) and \(T_\Sigma\), respectively; \(T_{\Sigma/E}\) is called the initial algebra of \((\Sigma, E)\). A theory inclusion \((\Sigma, E) \subseteq (\Sigma', E')\), with \(\Sigma \subseteq \Sigma' \) and \(E \subseteq E'\), is called protecting iff the unique \(\Sigma\)-homomorphism \(T_{\Sigma/E} \rightarrow T_{\Sigma/E}|_{\Sigma}\) to the \(\Sigma\)-reduct of the initial algebra \(T_{\Sigma/E}\) is a \(\Sigma\)-isomorphism, written \(T_{\Sigma/E} \simeq T_{\Sigma/E}|_{\Sigma}\). A set of equations \(E\) is called regular iff \(\text{vars}(t) = \text{vars}(u)\) for any equation \(t = u \in E\) if \(\gamma \in E\).

Appropriate requirements are needed to make an equational theory \(\mathcal{E}\) admissible, i.e., executable in rewriting language such as Maude [13]. It is assumed that the equations of \(\mathcal{E}\) can be decomposed into a disjoint union \(E \cup B\), with \(B\) a collection of structural axioms (such as associativity, and/or commutativity, and/or identity) for which there exists a matching algorithm modulo \(B\) producing a finite number of \(B\)-matching solutions, or failing otherwise, and that the equations \(E\) can be oriented into a set (of possibly conditional) sort-decreasing, operationally terminating, and confluent conditional rewrite rules \(\bar{\Theta}\) modulo \(B\). \(\bar{\Theta}\) is sort decreasing modulo \(B\) iff for each \(t \rightarrow u\) if \(\gamma \in \bar{\Theta}\) and substitution \(\theta, \text{ls}(t\theta) \geq \text{ls}(u\theta)\) if \((\Sigma, B, \bar{\Theta}) \vdash \gamma \theta\). \(\bar{\Theta}\) is operationally terminating modulo \(B\) if there is no infinite well-formed proof tree in \((\Sigma, B, \bar{\Theta})\). \(\bar{\Theta}\) is confluent modulo \(B\) iff all \(t_1, t_2 \in T_\Sigma(X)\), if \(t \rightarrow^*_{E/B} t_1\) and \(t \rightarrow^*_{E/B} t_2\), then there is \(u \in T_\Sigma(X)\) such that \(t_1 \rightarrow^*_{E/B} u\) and \(t_2 \rightarrow^*_{E/B} u\). The term \(t \downarrow_{E/B} \in T_\Sigma(X)\) denotes the \(E\)-canonical form of \(t\) modulo \(B\) so that \(t \rightarrow^*_{E/B} t \downarrow_{E/B}\) and \(t \downarrow_{E/B} \) cannot be further reduced by \(\rightarrow_{E/B}\). Under the above assumptions \(t \downarrow_{E/B}\) is unique up to \(B\)-equality.

A \(\Sigma\)-rule is a triple \(l \rightarrow r\) if \(\phi\), with \(l, r \in T_\Sigma(X)_s\), for some sort \(s \in S\), and \(\phi = \bigwedge_{i \in I} t_i = u_i\) a finite conjunction of \(\Sigma\)-equations. A rewrite theory is a tuple \(\mathcal{R} = (\Sigma, E, R)\) with \((\Sigma, E)\) an order-sorted equational theory and \(R\) a finite set of \(\Sigma\)-rules. \(\mathcal{R}\) induces a rewrite relation \(\rightarrow_{\mathcal{R}}\) on \(T_\Sigma(X)\) defined for every \(t, u \in T_\Sigma(X)\) by \(t \rightarrow_{\mathcal{R}} u\) if there is a rule \((l \rightarrow r\) if \(\phi\) \(\in R\) and a substitution \(\theta : X \rightarrow T_\Sigma(X)\) satisfying \(t =_E \theta l, u =_E r\theta\), and \(E \vdash \phi\theta\). Relation \(\rightarrow_{\mathcal{R}}\) is undecidable in general, unless conditions such as coherence [35] are given. A key point of this paper is to make such a relation decidable when \(E\) decomposes as \(E_0 \cup B_1\), where \(E_0\) is a built-in theory for which formula satisfiability is decidable and \(B_1\) has a matching algorithm. A topmost rewrite theory is a rewrite theory \(\mathcal{R} = (\Sigma, E, R)\), such that for some top sort \(\text{State}\), no operator in \(\Sigma\) has \(\text{State}\) as argument sort and each rule \(l \rightarrow r\) if \(\phi \in R\) satisfies \(l, r \in T_\Sigma(X)_{\text{State}}\) and \(\phi \not\in X\).

3 Rewriting Modulo a Built-in Subtheory

The concept of rewriting modulo a built-in equational subtheory is presented. In particular, the notion of rewrite theory modulo a built-in subtheory and its ground rewrite relation are introduced. A canonical representation for rewrite theories mod-
ulo built-ins is proposed, and some basic results are proved.

**Definition 1 (Signature with Built-ins).** An order-sorted signature \( \Sigma = (S, \leq, F) \) is a signature with built-in subsignature \( \Sigma_0 \subseteq \Sigma \) iff \( \Sigma_0 = (S_0, F_0) \) is many-sorted, \( S_0 \) is a set of minimal elements in \((S, \leq)\), and if \( f : w \rightarrow s \in F_1 \), then \( s \notin S_0 \) and \( f \) has no other typing in \( F_0 \), where \( F_1 = F \setminus F_0 \).

The notion of built-in subsignature in an order-sorted signature \( \Sigma \) is modeled by a many-sorted signature \( \Sigma_0 \) defining the built-in terms \( T_{\Sigma_0}(X_0) \). The restriction imposed on the sorts and the function symbols in \( \Sigma \) w.r.t. \( \Sigma_0 \) provides a clear syntactic distinction between built-in terms (the only ones with built-in sorts) and all other terms.

If \( \Sigma \supseteq \Sigma_0 \) is a signature with built-ins, then an abstraction of built-ins for \( t \) is a context \( \lambda x_1 \cdots x_n. t^0 \) such that \( t^0 \in T_{\Sigma_1}(X) \) and \( \{x_1, \ldots, x_n\} = \text{vars}(t^0) \cap X_0 \), where \( \Sigma_1 = (S, \leq,F_1) \) and \( X_0 = \{X_s\}_{s \in S_0} \). Lemma 1 shows that such an abstraction can be chosen so as to provide a canonical decomposition of \( t \) with useful properties.

**Lemma 1.** Let \( \Sigma \) be a signature with built-in subsignature \( \Sigma_0 = (S_0, F_0) \). For each \( t \in T_{\Sigma_1}(X) \), there exist an abstraction of built-ins \( \lambda x_1 \cdots x_n. t^0 \) for \( t \) and a substitution \( \theta^0 : X_0 \rightarrow T_{\Sigma_0}(X_0) \) such that (i) \( t = t^0 \theta \), (ii) \( \{x_1, \ldots, x_n\} \) are pairwise distinct and disjoint from \( \text{vars}(t) \), and (iii) \( \theta(x) = x \) if \( x \neq x_i \), for \( 1 \leq i \leq n \); moreover, (iv) \( t^0 \) can always be selected to be \( S_0 \)-linear and with \( \{x_1, \ldots, x_n\} \) disjoint from an arbitrarily chosen finite subset \( Y \) of \( X_0 \).

**Proof.** By induction on the structure of \( t \).

In the rest of the paper, for any \( t \in T_{\Sigma_1}(X) \) and \( Y \subseteq X_0 \) finite, the expression \( \text{abstract}_{\Sigma_1}(t, Y) \) denotes the choice of a triple \( \langle \lambda x_1 \cdots x_n. t^0; \theta^0; \phi^0 \rangle \) such that the context \( \lambda x_1 \cdots x_n. t^0 \) and the substitution \( \theta^0 \) satisfy the properties (i)–(iv) in Lemma 1, and \( \phi^0 = \wedge_{i=1}^{n} (x_i = \theta^0(x_i)) \).

Under certain restrictions on axioms, matching a \( \Sigma \)-term \( t \) to a \( \Sigma \)-term \( u \), can be decomposed modularly into \( \Sigma_1 \)-matching of the corresponding \( \lambda \)-abstraction and \( \Sigma_0 \)-matching of the built-in subterms. This is described in Lemma 2. The proof of this lemma uses the following corollary.

**Corollary 1.** Let \( \Sigma = (S, \leq, F) \) be a signature with built-in subsignature \( \Sigma_0 = (S_0, F_0) \). Let \( B_0 \) be a set of \( \Sigma_0 \)-axioms and \( B_1 \) a set of \( \Sigma_1 \)-axioms. For \( B_0 \) and \( B_1 \) regular, linear, collapse-free for any sort in \( S_0 \), and sort-preserving, and \( t \in T_{\Sigma}(X) \):

(a) if \( t \in T_{\Sigma_0}(X_0) \) and \( t =^1_{B_1} t' \), then \( t = t' \);
(b) if \( t \in T_{\Sigma_1}(X) \) and \( t =^1_{B_0} t' \), then \( t = t' \);
(c) if \( t \in T_{\Sigma_1}(X) \) and \( t =^1_{B_1} t' \), then \( \text{vars}(t) = \text{vars}(t') \) and \( t \) is linear iff \( t' \) is so;

**Proof.**

(a) Axioms \( B_1 \) do not mention any function symbol in \( F_0 \). Therefore, the equation in \( B_0 \) can only apply to variables in \( X_0 \). But \( B_1 \) is collapse-free for any sort in \( S_0 \), so that no \( B_1 \) equation can be applied to \( t \), forcing \( t = t' \).
(b) Same argument as (a).

(c) Trivial consequence of $B_1$ being regular and linear.

Lemma 2. Let $\Sigma = (S, \leq, F)$ be a signature with built-in subsignature $\Sigma_0 = (S_0, F_0)$. Let $B_0$ be a set of $\Sigma_0$-axioms and $B_1$ a set of $\Sigma_1$-axioms. For $B_0$ and $B_1$ regular, linear, collapse free for any sort in $S_0$, and sort-preserving, if $t \in T_{\Sigma_1}(X_0)$ is linear with $\text{vars}(t) = \{x_1, \ldots, x_n\}$, then for each $\theta : X_0 \rightarrow T_{\Sigma_0}(X_0)$:

(a) if $t\theta = _{B_0} t'$, then there exist $x \in \{x_1, \ldots, x_n\}$ and $w \in T_{\Sigma_0}(X_0)$ such that $\theta(x) = _{B_0} w$ and $t' = t\theta'$, with $\theta'(x) = w$ and $\theta'(y) = \theta(y)$ otherwise;

(b) if $t\theta = _{B_1} t'$, then there exists $v \in T_{\Sigma_1}(X_0)$ such that $t = _{B_1} v$ and $t' = v\theta$; and

(c) if $t\theta = _{B_0 \uplus B_1} t'$, then there exist $v \in T_{\Sigma_1}(X_0)$ and $\theta' : X_0 \rightarrow T_{\Sigma_0}(X_0)$ such that $t' = v\theta'$, $t = _{B_1} v$, and $\theta = _{B_0} \theta'$ (i.e., $\theta(x) = _{B_0} \theta'(x)$ for each $x \in X_0$).

Proof. (a) It follows from Corollary 1 part (b) that $B_0$ can only be applied on some built-in subterm $\theta(x)$ of $t\theta$, for some $x \in \text{dom}(\theta)$. That is, there is $w \in T_{\Sigma_0}(X_0)$ such that $\theta(x) = _{B_0} w$ and, since $t$ is linear, $t' = t\theta'$, where $\theta'(x) = w$ and $\theta'(y) = \theta(y)$ otherwise.

(b) It follows from Corollary 1 part (c) that equational deduction with $B_1$ can only permute the built-in variables in $t$ and it does not equate built-in subterms such as the ones in $\text{ran}(\theta)$. Hence, by Corollary 1 part (c), there exists a linear $v \in T_{\Sigma_1}(X_0)$ such that $t = _{B_1} v$ and $t' = v\theta$.

(c) Follows by induction on the proof’s length in $B_0 \uplus B_1$. 

Definition 2 introduces the notion of rewriting modulo a built-in subtheory.

Definition 2 (Rewriting Modulo a Built-in Subtheory). A rewrite theory modulo the built-in subtheory $\mathcal{E}_0$ is a topmost rewrite theory $\mathcal{R} = (\Sigma, E, R)$ with:

(a) $\Sigma = (S, \leq, F)$ a signature with built-in subsignature $\Sigma_0 = (S_0, F_0)$ and top sort $\text{State} \in S$;

(b) $E = E_0 \uplus B_0 \uplus B_1$, where $E_0$ is a set of $\Sigma_0$-equations, $B_0$ (resp., $B_1$) are $\Sigma_0$-axioms (resp., $\Sigma_1$-axioms) satisfying the conditions in Lemma 2, $\mathcal{E}_0 = (\Sigma_0, E_0 \uplus B_0)$ and $\mathcal{E} = (\Sigma, E)$ are admissible, and the theory inclusion $\mathcal{E}_0 \subseteq \mathcal{E}$ is protecting;

(c) $R$ is a set of rewrite rules of the form $l(\overrightarrow{x_1}, \overrightarrow{y}) \rightarrow r(\overrightarrow{x_2}, \overrightarrow{y'})$ if $\phi(\overrightarrow{x_3})$ such that $l, r \in T_{\Sigma}(\text{State})$, $l$ is $(S \setminus S_0)$-linear, $\overrightarrow{x_i}; \overrightarrow{s_i}$ with $\overrightarrow{s_i} \in S_0^i$, for $i \in \{1, 2, 3\}$, $\overrightarrow{y}; \overrightarrow{s'}$ with $\overrightarrow{s'} \in (S \setminus S_0)^*$, and $\phi \in \text{QF}_{\Sigma_0}(X_0)$, where $\text{QF}_{\Sigma_0}(X_0)$ denotes the set of quantifier-free $\Sigma_0$-formulas with variables in $X_0$. 

6
Note that, due to the presence of conditions $\phi$ in the rules of $R$ that are general quantifier-free formulas, as opposed to a conjunction of atoms, properly speaking $R$ is somewhat more general than a standard rewrite theory as defined in Section 2.

The binary rewrite relation induced by a rewrite theory $R$ modulo $E_0$ on $T_{\Sigma, State}$ is called the ground rewrite relation of $R$.

**Definition 3 (Ground Rewrite Relation).** Let $R = (\Sigma, E, R)$ be a rewrite theory modulo $E_0$. The relation $\rightarrow_R$ induced by $R$ on $T_{\Sigma, State}$ is defined for $t, u \in T_{\Sigma, State}$ by $t \rightarrow_R u$ iff there is a rule $l \rightarrow r$ if $\phi$ in $R$ and a ground substitution $\sigma : X \rightarrow T_\Sigma$ such that (a) $l =_E l \sigma$, $u =_E r \sigma$, and (b) $T_{E_0} \models \phi \sigma$.

The ground rewrite relation $\rightarrow_R$ is the topmost rewrite relation induced by $R$ modulo $E$ on $T_{\Sigma, State}$. This relation is defined even when a rule in $R$ has extra variables in its right-hand side: the rule is then non-deterministic and such extra variables can be arbitrarily instantiated, provided that the corresponding instantiation of $\phi$ holds. Also, note that non built-in variables can occur in $l$, but $\phi \sigma$ is a variable-free formula in $QF_{\Sigma_0}(0)$, so that either $T_{E_0} \models \phi \sigma$ or $T_{E_0} \not\models \phi \sigma$.

A rewrite theory $R$ modulo $E_0$ always has a canonical representation in which all left-hand sides of rules are linear $\Sigma_1$-terms.

**Definition 4 (Normal Form of a Rewrite Theory Modulo $E_0$).** Let $R = (\Sigma, E, R)$ be a rewrite theory modulo $E_0$. Its normal form $R^0 = (\Sigma, E, R^0)$ has rules:

\[ R^0 = \{ l^0 \rightarrow r^{\phi} \land \phi^0 \mid (\exists l \rightarrow r \text{ if } \phi \in R)(\lambda x. l^0 \land \phi^0) = \text{abstract}_\Sigma(l, \text{vars}(\{l, r, \phi\})) \}. \]

**Lemma 3 (Invariance of Ground Rewriting under Normalization).** Let $R = (\Sigma, E, R)$ be a rewrite theory modulo $E_0$. Then $\rightarrow_R = \rightarrow_{R^0}$.

**Proof.** We show that $\rightarrow_R \subseteq \rightarrow_{R^0}$ and $\rightarrow_{R^0} \subseteq \rightarrow_R$.

$(\subseteq)$ Let $t, u \in T_{\Sigma, State}$. If $t \rightarrow_R u$, then there is a rule $(l \rightarrow r \text{ if } \phi) \in R$ and a ground substitution $\sigma : X \rightarrow T_\Sigma$ such that $t =_E l \sigma$, $u =_E r \sigma$, and $T_{E_0} \models \phi \sigma$. It suffices to prove $t \rightarrow_{R^0} u$ with witnesses $(l^0 \rightarrow r^{\phi} \land \phi^0) \in R^0$ and $\rho = \theta^0 \sigma$. Note that $t =_E l \sigma = l^0 \theta^0 \sigma = l^0 \rho$. For $T_{E_0} \models (\phi \land \phi^0) \rho$ first note that $T_{E_0} \models \phi \rho$ since $\phi \rho = \phi^0 \sigma = \phi \sigma$ (because $\text{vars}(\phi) \cap \text{dom}(\theta^0) = \emptyset$) and $T_{E_0} \models \phi \sigma$ by assumption. For $T_{E_0} \models \phi^0 \rho$ notice that $\theta^0 \rho = \rho$ because $\text{ran}(\theta^0) \cap \text{dom}(\theta^0) = \emptyset$, and then:

\[
\phi^0 \rho = \left( \bigwedge_{i=1}^{n} x_i = \theta^0(x_i) \right) \rho = \bigwedge_{i=1}^{n} x_i \rho = \theta^0(x_i) \rho = \bigwedge_{i=1}^{n} \theta^0(x_i) \sigma = \theta^0(x_i) \theta^0 \sigma = \top.
\]

Hence $t \rightarrow_{R^0} u$ as desired.

$(\supseteq)$ Let $t, u \in T_{\Sigma, State}$. If $t \rightarrow_{R^0} u$, then there is a rule $(l \rightarrow r \text{ if } \phi) \in R$ and a ground substitution $\sigma : X \rightarrow T_\Sigma$ such that $t =_E l^0 \sigma$, $u =_E r \sigma$, and $T_{E_0} \models (\phi \land \phi^0) \sigma$. It suffices to prove $t \rightarrow_R u$ with witness $(l \rightarrow r \text{ if } \phi) \in R$. 

7
Let \( \langle \lambda x_1 \cdots x_n. l^0 : \theta^0 ; \phi^0 \rangle \) be the abstraction of built-ins for \( l \). Substitution \( \sigma \) can be decomposed into substitutions \( \theta : X_0 \rightarrow T_{\Sigma_0}(X_0) \) and \( \rho : X \rightarrow T_{\Sigma} \) with \( \theta(x) = \sigma(x) \) if \( x \in \{ x_1, \ldots, x_n \} \) and \( \theta(x) = x \) otherwise, such that \( \sigma = \theta \rho \). From \( T_{\Sigma_0} \models (\phi \land \phi^0) \sigma \) it follows that \( T_{E_0} \models \phi \sigma \), i.e., \( T_{E_0} \models \phi \rho \) because \( \text{vars}(\phi) \cap \text{dom}(\theta) = \emptyset \). Also, it follows that \( T_{E_0} \models \bigwedge_{i=1}^n \theta(x_i) \rho = \theta^0(x_i) \rho \) which implies that:

\[
t = E \cdot t^0 \sigma = l^0 \theta \rho = E_{ij} B_0 l^0 \rho = l^0 \rho.
\]

Hence \( t \rightarrow^R u \), as desired.

\[
\square
\]

By the properties of the axioms in a rewrite theory modulo built-ins \( R = (\Sigma, E_0 \uplus B_0 \uplus B_1) \), \( B_1 \)-matching a term \( t \in T_{\Sigma}(X_0) \) to a left-hand side \( l^0 \) of a rule in \( R^0 \) provides a complete unifiability algorithm for ground \( B_1 \)-unification of \( t \) and \( l^0 \).

**Lemma 4 (Matching Lemma).** Let \( R = (\Sigma, E_0 \uplus B_0 \uplus B_1, R) \) be a rewrite theory modulo \( E_0 \). For \( t \in T_{\Sigma}(X_0) \) and \( l^0 \) a left-hand side of a rule in \( R^0 \) such that \( \text{vars}(t) \cap \text{vars}(l^0) \), \( t \ll_{B_1} l^0 \) iff \( \text{GU}_{B_1}(t = l^0) \neq \emptyset \) holds, where \( \text{GU}_{B_1}(t = l^0) = \{ \sigma : X \rightarrow T_{\Sigma} \mid t \sigma = B_1 l^0 \sigma \} \).

**Proof.**

(\( \Rightarrow \)) If \( t \ll_{B_1} l^0 \), then \( t = B_1 l^0 \theta \) for some \( \theta : X \rightarrow T_{\Sigma}(X) \). Let \( \rho : X \rightarrow T_{\Sigma} \) be any ground substitution. Then \( \theta \rho \in \text{GU}_{B_1}(t = l^0) \).

(\( \Leftarrow \)) Let \( \sigma \in \text{GU}_{B_1}(t = l^0) \) with \( l \rightarrow^R \phi \) if \( \phi \in R \). Let \( \text{vars}(l^0) \cap X_0 = \{ x_1, \ldots, x_n \} \) and \( X_1 = X \setminus X_0 \). Note that there are substitutions

\[
\alpha : \text{vars}(l^0) \cap X_1 \rightarrow T_{\Sigma_1}(X_0)
\]

\[
\rho : X \setminus \text{dom}(\alpha) \rightarrow T_{\Sigma}
\]

satisfying \( \sigma = \alpha \rho \) and such that \( (l^0 \alpha) \in T_{\Sigma_1}(X_0) \) is linear and \( \text{ran}(l^0 \alpha) \cap \text{vars}(t, l^0) = \emptyset \). Let \( \text{ran}(\alpha) = \{ y_1, \ldots, y_m \} \). Therefore, by Lemma 2, there exists \( u \in T_{\Sigma_1}(X_0) \) such that \( u = B_1 l^0 \alpha, u \) is linear, and \( \text{vars}(u) = \text{vars}(l^0 \alpha) = x_1, \ldots, x_n, y_1, \ldots, y_m \), and \( \alpha \rho = t \). Moreover, \( t \) can be written as

\[
u(t_1, \ldots, t_n, t_{n+1}, \ldots, t_{n+m})
\]

with \( t_i \in T_{\Sigma_0}(X_0) \). Define \( \theta : X_0 \rightarrow T_{\Sigma_0}(X_0) \) by \( \theta(x) = t_i \) if \( x \in \{ x_1, \ldots, x_n \} \), \( \theta(x) = t_{i+n} \) if \( x \in \{ y_1, \ldots, y_m \} \), and \( \theta(x) = x \) otherwise. Then we have:

\[
t = u(t_1, \ldots, t_n, t_{n+1}, \ldots, t_{n+m})
\]

\[
= u(x_1, \ldots, x_n, y_1, \ldots, y_m) \theta
\]

\[
= B_1 l^0 \alpha \theta.
\]

Therefore, \( t \ll_{B_1} l^0 \), as desired.

\[
\square
\]
4 Symbolic Rewriting Modulo a Built-in Subtheory

We explain how a rewrite theory $\mathcal{R}$ modulo $\mathcal{E}_0$ defines a symbolic rewrite relation on terms in $T_{\mathcal{E}_0}(X_0)_{\text{State}}$ constrained by formulas in $QF_{\mathcal{E}_0}(X_0)$. The idea is that, when $\mathcal{E}_0$ is a decidable theory, transitions on the symbolic terms can be performed by rewriting modulo $B_1$, and satisfiability of the formulas can be handled by an SMT decision procedure. This approach provides an efficiently executable symbolic method called rewriting modulo SMT that is sound and complete with respect to the ground rewrite relation of Definition 3 and yields a complete symbolic reachability analysis method.

Definition 5 (Constrained Terms and their Denotation). Let $\mathcal{R} = (\Sigma, E, R)$ be a rewrite theory modulo $\mathcal{E}_0$. A constrained term is a pair $(t; \varphi)$ in $T_{\Sigma}(X_0)_{\text{State}} \times QF_{\mathcal{E}_0}(X_0)$. Its denotation $[[t]]_{\varphi}$ is defined as

$$[[t]]_{\varphi} = \{ t' \in T_{\Sigma, \text{State}} \mid (\exists \sigma : X_0 \longrightarrow T_{\Sigma_0}) \ t' = t \sigma \land \mathcal{E}_0 \models \varphi \sigma \}.$$  

The domain of $\sigma$ in Definition 5 ranges over all built-in variables $X_0$ and consequently $[[t]]_{\varphi} \subseteq T_{\Sigma, \text{State}}$ for any $t \in T_{\Sigma}(X_0)_{\text{State}}$, even if $\text{vars}(t) \not\subseteq \text{vars}(\varphi)$. Intuitively, $[[t]]_{\varphi}$ denotes the set of all ground states that are instances of $t$ and satisfy $\varphi$.

Before introducing the symbolic rewrite relation on constrained terms induced by a rewrite theory $\mathcal{R}$ modulo $\mathcal{E}_0$, auxiliary notation for variable renaming is required. In the rest of the paper, the expression $\text{fresh-vars}(Y)$, for $Y \subseteq X$ finite, represents a variable renaming $\varsigma : X \longrightarrow X$ satisfying $Y \cap \text{ran}(\varsigma) = \emptyset$.

Definition 6 (Symbolic Rewrite Relation). Let $\mathcal{R} = (\Sigma, E, R)$ be a rewrite theory modulo built-ins $\mathcal{E}_0$. The symbolic rewrite relation $\sim_{\mathcal{R}}$ induced by $\mathcal{R}$ on $T_{\Sigma}(X_0)_{\text{State}} \times QF_{\mathcal{E}_0}(X_0)$ is defined for $t, u \in T_{\Sigma}(X_0)_{\text{State}}$ and $\varphi, \varphi' \in QF_{\mathcal{E}_0}(X_0)$ by $\langle t ; \varphi \rangle \sim_{\mathcal{R}} \langle u ; \varphi' \rangle$ iff there is a rule $l \rightarrow r$ in $R$ and a substitution $\theta : X \longrightarrow T_{\Sigma}(X)$ such that (a) $t =_E l \varsigma \theta$ and $u = r \varsigma \theta$, (b) $\mathcal{E}_0 \vdash (\varphi \iff \varphi' \land \phi \varsigma \theta)$, and (c) $\varphi'$ is $T_{\mathcal{E}_0}$-satisfiable, where $\varsigma = \text{fresh-vars}(\text{vars}(t, \varphi))$.

The symbolic relation $\sim_{\mathcal{R}}$ on constrained terms is defined as a topmost rewrite relation induced by $R$ modulo $E$ on $T_{\Sigma}(X_0)$ with extra bookkeeping of constraints. Note that $\varphi'$ in $\langle t ; \varphi \rangle \sim_{\mathcal{R}} \langle u ; \varphi' \rangle$, when witnessed by $l \rightarrow r$ if $\phi$ and $\theta$ is semantically equivalent to $\varphi \land \phi \varsigma \theta$, in contrast to being syntactically equal. This extra freedom allows for simplification of constraints if desired. Also, such a constraint $\varphi'$ is satisfiable in $T_{\mathcal{E}_0}$, implying that $\varphi$ and $\phi \theta$ are both satisfiable in $T_{\mathcal{E}_0}$, and therefore $[[t]]_{\varphi} \neq \emptyset \neq [[u]]_{\varphi'}$. Note that, up to the choice of the semantically equivalent $\varphi'$ for which a fixed strategy is assumed, the symbolic relation $\sim_{\mathcal{R}}$ is deterministic because the renaming of variables in the rules is fixed by fresh-vars. This is key when executing $\sim_{\mathcal{R}}$, as explained in Section 5.

The important question to ask is whether this symbolic relation soundly and completely simulates its ground counterpart. The rest of this section answers this question in the affirmative for normalized rewrite theories modulo built-ins. Thanks to Lemma 3, the conclusion is therefore that $\sim_{\mathcal{R}}$ soundly and completely simulates $\rightarrow_{\mathcal{R}}$ for any rewrite theory $\mathcal{R}$ modulo built-ins $\mathcal{E}_0$. 

9
The soundness of $\rightsquigarrow_{R_0}$ w.r.t. $\rightarrow_{R_0}$ is stated and proved in Theorem 1. Intuitively, soundness means that a pair $(t; \varphi) \rightsquigarrow_{R_0} (u; \varphi')$ is a symbolic underapproximation of all pairs such that $t' \rightarrow_{R_0} u'$ with $t' \in [t]_\varphi$ and $u' \in [u]_{\varphi'}$.

**Theorem 1 (Soundness).** Let $R = (\Sigma, E, R)$ be a rewrite theory modulo built-ins $\mathcal{E}_0$, $t, u \in T_\Sigma(X_0)_{\text{State}}$, and $\varphi, \varphi' \in QF_{\Sigma_0}(X_0)$. If $(t; \varphi) \rightsquigarrow_{R_0} (u; \varphi')$, then $t \rho \rightarrow_{R_0} u \rho$ for all $\rho : X_0 \rightarrow T_\Sigma$, satisfying $T_{\mathcal{E}_0} \models \varphi' \rho$.

**Proof.** Let $\rho : X_0 \rightarrow T_\Sigma$ satisfy $T_{\mathcal{E}_0} \models \varphi' \rho$. The goal is to show that $t \rho \rightarrow_{R_0} u \rho$. Let $l^0 \rightarrow_r r$ if $\phi \in R^0$ and $\theta : X_0 \rightarrow T_0(X_0)$ witness $(t; \varphi) \rightsquigarrow_{R_0} (u; \varphi')$. Then $t = E l^0 \chi, u = E r \chi$, $\mathcal{E}_0 \vdash (\varphi' \leftrightarrow \varphi \land \phi \chi)$, and $\varphi'$ is $T_{\mathcal{E}_0}$-satisfiable. Without loss of generality assume that $\theta_{\text{vars}(t, \varphi)} = \mathit{id}_{\text{vars}(t, \varphi)}$ and let $\sigma = \chi \rho$. Then note that $t \rho = E l^0 \chi \rho = l^0 \chi \rho \sigma = l^0 \sigma$ and $u \rho = E r \chi \rho = r \chi \sigma = r \sigma$. Moreover, $T_{\mathcal{E}_0} \models (\varphi' \leftrightarrow \varphi \land \phi \chi)$ and $T_{\mathcal{E}_0} \models \varphi' \rho$ imply $T_{\mathcal{E}_0} \models \phi \chi \rho$, i.e., $T_{\mathcal{E}_0} \models \phi \sigma$. Therefore, $t \rho \rightarrow_{R_0} u \rho$, as desired.

The completeness of $\rightsquigarrow_{R_0}$ w.r.t. $\rightarrow_{R_0}$ is stated and proved in Theorem 2, which is a “lifting lemma”. Intuitively, completeness states that a symbolic relation yields an over-approximation of its ground rewriting counterpart.

**Theorem 2 (Completeness).** Let $R = (\Sigma, E, R)$ be a rewrite theory modulo built-ins $\mathcal{E}_0$, $t \in T_\Sigma(X_0)_{\text{State}}$, $u' \in T_{\Sigma(\mathcal{E}_0)}$, and $\varphi \in QF_{\Sigma_0}(X_0)$. For any $\rho : X_0 \rightarrow T_\Sigma$ such that $t \rho \in [t]_\varphi$ and $t \rho \rightarrow_{R_0} u'$, there exist $u \in T_{\Sigma(X_0)}_{\text{State}}$ and $\varphi' \in QF_{\Sigma_0}(X_0)$ such that $(t; \varphi) \rightsquigarrow_{R_0} (u; \varphi')$ and $u' \in [u]_{\varphi'}$.

**Proof.** By the assumptions there is a rule $(l^0 \rightarrow_r r$ if $\phi) \in R^0$ and a ground substitution $\sigma : X \rightarrow T_{\Sigma}$ satisfying $t \rho = E l^0 \sigma$, $u' = E r \sigma$, and $T_{\mathcal{E}_0} \models \phi \sigma$. Without loss of generality assume $\text{vars}(t, \varphi) \cap \text{vars}(l^0, r, \varphi) = \emptyset$; otherwise $l, r, \varphi$ can be renamed by means of fresh-vars. Furthermore, $\sigma = \rho$ can be assumed. The goal is to show the existence of $u \in T_{\Sigma(X \text{State})}$ and $\varphi' \in QF_{\Sigma_0}(X_0)$ such that (i) $(t; \varphi) \rightsquigarrow_{R_0} (u; \varphi')$ and (ii) $u' \in [u]_{\varphi'}$. Since $l^0$ is linear and built-in subterms are variables, by Lemma 2 there exists $\alpha : X \rightarrow T_{\Sigma}$ satisfying $t \alpha = B_1 l^0 \alpha$. Hence $G U_{B_1}(t = l^0 \alpha \neq 0$ and, by Lemma 4, there exists $t' : X \rightarrow T_{\Sigma}(X)$ satisfying $t = B_1 l^0 t'$. Let $\theta : X \rightarrow T_{\Sigma}(X)$ be defined by $\theta(\alpha) = \theta(x) = \theta'\alpha(x) \notin \text{vars}(l)$ and $\theta(\alpha) = \rho(x)$ otherwise. Note that $\theta_{\text{vars}(l)} \rho = E \theta_{\text{vars}(B_0)} \rho_{\text{vars}(l)}$. Define $u = r \theta$ and $\varphi' = \varphi \land \phi \theta$, and then for (i) and (ii) above:

(i) It suffices to prove that $T_{\mathcal{E}_0} \models \varphi' \rho$, i.e., $T_{\mathcal{E}_0} \models (\varphi \land \phi \theta) \rho$. By assumption $T_{\mathcal{E}_0} \models \varphi \rho$ and $T_{\mathcal{E}_0} \models \phi \rho$. Notice that:

\[
\phi \theta \rho = (\phi \theta_{\text{vars}(l)}) \rho = E \theta_{\text{vars}(l)} (\phi \rho) \rho = \phi \rho.
\]

Hence $T_{\mathcal{E}_0} \models \phi \theta \rho$.

(ii) By assumption $u' = E u_{\text{vars}(l)} r \rho$; also:

\[
r \rho = E u_{\text{vars}(l)} r \rho_{\text{vars}(l)} \rho = r \theta \rho = u \rho.
\]

Hence $u' = E u_{\text{vars}(l)} u \rho \in [u]_{\varphi'}$ by part (i).
Although the above soundness and completeness theorems, plus Lemma 3, show that $\rightarrow_{R}$ is fully characterized symbolically by $\sim_{R}$, for any rewrite theory $R$ modulo $E_0$, because of condition (6) in Definition 6, the relation $\sim_{R}$ is in general undecidable. However, $\sim_{R}$ becomes decidable for built-in theories $E_0$ that can be extended to a \textit{decidable theory $E_0^{+}$} (typically by adding some inductive consequences) such that:

$$\forall \phi \in QF_{\Sigma_0}(X_0) \phi \in E_0^{+} \iff (\exists \sigma : X_0 \rightarrow T_{\Sigma_0}) \; T_{E_0} \models \phi \sigma. \quad (1)$$

Many decidable theories $E_0^{+}$ of interest are supported by SMT solvers satisfying this requirement. For example, $E_0$ can be the equational theory of natural number addition and $E_0^{+}$ Pressburger arithmetic. That is, $T_{E_0}$ is the \textit{standard model} of both $E_0$ and $E_0^{+}$, and $E_0^{+}$-satisfiability coincides with satisfiability in such a standard model. Under such conditions, satisfiability of $\phi \cap \phi \cap \theta$ (and therefore of $\phi'$) in a step $\langle t; \varphi \rangle \sim_{E_0} \langle u; \varphi' \rangle$ becomes decidable by invoking an SMT-solver for $E_0$, so that $\sim_{E_0}$ can be naturally described as \textit{symbolic rewriting modulo SMT} (and modulo $B_1$).

The symbolic reachability problems considered for a rewrite theory $R$ modulo $E_0$ in this paper, are existential formulas of the form $(\exists \overrightarrow{x}) \; t \rightarrow^* u \land \varphi$, with $\overrightarrow{x}$ the variables appearing in $t$, $u$, and $\varphi$, $t \in T_{\Sigma}(X_0)$, $u \in T_{\Sigma}(X)$, and $\varphi \in QF_{\Sigma_0}(X_0)$. By abstracting the $\Sigma_0$-subterms of $u$, the ground solutions of such a reachability problem are those witnessing the model-theoretic satisfaction relation:

$$T_R \models (\exists \overrightarrow{x} \cup \overrightarrow{y}) \; t(\overrightarrow{x}) \rightarrow^* u^\sigma(\overrightarrow{y}) \land \varphi_1(\overrightarrow{x}) \land \varphi_2(\overrightarrow{x}, \overrightarrow{y}) \quad (2)$$

where $T_R = (T_{\Sigma/E_0}, \rightarrow_R)$ is the initial reachability model of $R$ [11], $t \in T_{\Sigma}(X)$ and $u^\sigma \in T_{\Sigma}(X)$ are $S_0$-linear, $\text{vars} (t) \subseteq \overrightarrow{x} \subseteq X_0$, and $\overrightarrow{y} \subseteq X$. Thanks to the soundness and completeness results, theorems 1 and 2, the solvability of Condition (2) for $\rightarrow_R$ can be achieved by reachability analysis with $\sim_{R}$. This is stated and proved in Theorem 3.

**Theorem 3** (Symbolic Reachability Analysis). Let $R = (\Sigma, E, R)$ be a rewrite theory modulo built-ins $E_0$. The reachability problem in Condition (2) has a solution if there exist a term $v \in T_{\Sigma}(X)$, a constraint $\varphi' \in QF_{\Sigma_0}(X_0)$, and a substitution $\theta : X \rightarrow T_{\Sigma}(X)$, with $\text{dom} (\theta) \subseteq \overrightarrow{y}$, such that (a) $\langle t; \varphi_1 \rangle \sim_{R} \langle v; \varphi' \rangle$, (b) $v =_{B_1} u^\sigma\theta$, and (c) $\varphi' \land \varphi_2 \theta$ is $T_{E_0}$-satisfiable.

**Proof.** By theorems 1 and 2, and induction on the length of the rewrite derivation.

In Theorem 3, since $\text{dom} (\theta) \subseteq \overrightarrow{y}$, and $\overrightarrow{x}$ and $\overrightarrow{y}$ are disjoint, the variables of $\overrightarrow{x}$ in $\varphi_2 \theta$ are left unchanged. Therefore, $\varphi_2 \theta$ \textit{links} the requirements for the variables $\overrightarrow{x}$ in the initial state and $\overrightarrow{y}$ in the final state according to both $\varphi_1$ and $\varphi_2$. Also note that the inclusion of formula $\varphi_1$ as a conjunct in the formula in Condition (3) of Theorem 3 is superfluous because $\langle t; \varphi_1 \rangle \sim_{R} \langle v; \varphi' \rangle$ implies that $\varphi_1$ is a semantic consequence of $\varphi'$. 

\[\square\]
5 Reflective Implementation of $\rightsquigarrow R_0$

The design and implementation of prototype that offers support for rewriting modulo SMT in the Maude system are discussed. The prototype relies on Maude’s metalevel features, that implement rewriting logic’s reflective capabilities, and on SMT solving for $E^+_0$ integrated in Maude as CVC3’s decision procedures. The extension of Maude with CVC3 is available from the Matching Logic Project [33]. In the rest of this section, $\mathcal{R} = (\Sigma, E_0 \uplus B_0 \uplus B_1, R)$ is a rewrite theory modulo built-ins $\mathcal{E}_0$, where $\mathcal{E}_0$ satisfies Condition (1) in Section 4. The theory mapping $\mathcal{R} \mapsto u(\mathcal{R})$ removes the constraints from the rules in $R$ and interprets the built-in variables $X_0$ as constants.

In Maude, reflection is efficiently supported by its META-LEVEL module [13], which provides key functionality for rewriting logic’s universal theory $\mathcal{U}$ [14]. Rewrite theories $\mathcal{R}$ are meta-represented in $\mathcal{U}$ as terms $\overline{\mathcal{R}}$ of sort Module, and a term $t$ in $\mathcal{R}$ is meta-represented in $\mathcal{U}$ as a term $\overline{t}$ of sort Term. The key idea of the reflective implementation is to reduce symbolic rewriting with $\rightsquigarrow R_0$ to standard rewriting in an associated reflective rewrite theory extending the universal theory $\mathcal{U}$. This is specially important for formal analysis purposes, because it makes available to $\rightsquigarrow R_0$ some formal analysis features provided by Maude for rewrite theories such as reachability analysis by search. This is illustrated by the case study in Section 6.

The prototype defines a parametrized functional module $\text{SAT}(\Sigma_0, E_0 \uplus B_0)$ of quantifier-free formulas with $\Sigma_0$-equations as atoms. This module extends $(\Sigma_0, E_0 \uplus B_0)$ with new sorts Atom and QFFormula, and new constants $\text{var}(X_0)$ identifying the variables $X_0$. It has, among other functions, a function $\text{sat} : \text{QFFormula} \rightarrow \text{Bool}$ such that for $\phi$, $\text{sat}(\phi) = \top$ if $\phi$ is $\mathcal{E}_0^+$-satisfiable, and $\text{sat}(\phi) = \bot$ otherwise.

The process of computing the one-step rewrites of a given constrained term $\langle t; \varphi \rangle$ under $\rightsquigarrow R_0$ is decomposed into two conceptual steps using Maude’s metalevel. First, all possible triples $\langle u; \theta; \phi \rangle$ such that $t \rightsquigarrow u(\mathcal{R})$ $u$ is witnessed by a matching substitution $\theta$ and a rule with constraint $\phi$ are computed\(^1\). Second, these triples are filtered out by keeping only those for which the quantifier-free formula $\varphi \land \phi \theta$ is $\mathcal{E}_0^+$-satisfiable.

The first step in the process is mechanized by function $\text{next}$, available from the parametrized module $\text{NEXT}(\overline{\mathcal{R}}, \text{State}, \text{QFFormula})$ where $\overline{\mathcal{R}}$, State, and QFFormula are the metalevel representations, respectively, of the rewrite theory module $\mathcal{R}$, the state sort $\text{State}$, and the quantifier-free formula sort $\text{QFFormula}$. Function $\text{next}$ uses Maude’s meta-match function and the auxiliary function $\text{new-vars}$ for computing fresh variables (see Section 4). The call

$$\text{next}(((S; \leq, F \uplus \text{var}(X_0)), E_0 \uplus B_0 \uplus B_1, R^c), \overline{t}, \overline{\varphi})$$

computes all possible triples $\langle \overline{u}; \overline{\theta}; \overline{\phi} \rangle$ such that $t \rightsquigarrow u(\mathcal{R})$ $u$ is witnessed by a substitution $\theta'$ and a rule with constraint $\phi'$. More precisely, such a call first computes a renaming $\zeta = \text{fresh-vars}(\text{vars}(t, \varphi))$ and then, for each rule $(l^0 \rightarrow r \text{ if } \phi)$, it uses the function meta-match to obtain a substitution

$$\overline{\theta} \in \text{meta-match}(((S; \leq, F \uplus \text{var}(X_0)), B_0 \uplus B_1), \overline{t}, \overline{\varphi}, l^0 \downarrow_{E_0/B_0 \uplus B_1, \overline{\varphi}}), \overline{\varphi} \zeta),$$

\(^1\)Note that in $u(\mathcal{R})$ variables in $X_0$ are interpreted as constants. Therefore, the number of matching substitutions $\theta$ thus obtained is finite.
and returns $\langle \pi; \vartheta'; \varphi' \rangle$ with $\pi = r \zeta \theta$, $\vartheta' = \zeta \theta$, and $\varphi' = \delta \zeta \theta$. Note that by having a deterministic choice of fresh variables (including those in the constraint), function $\text{next}$ is actually a deterministic function.

Using the above-mentioned infrastructure, the parametrized module $\text{NEXT}$ implements the symbolic rewrite relation $\rightsquigarrow_{R^0}$ as a standard rewrite relation in the theory $\text{NEXT}$, extending $\text{META-LEVEL}$, by means of the following conditional rewrite rule:

$$
\text{ceq} \quad \langle X; \text{State}; \varphi; \text{QFFormula} \rangle \rightarrow \langle Y; \text{State}; \varphi'; \text{QFFormula} \rangle \\
\text{if } \langle Y; \theta'; \varphi \rangle \leftarrow \text{next}(R^0, X, \varphi) \land \text{sat}(\varphi) = \top \land \varphi' := \varphi \land \phi
$$

where $R^* = ((S, \leq, F \uplus \text{var}(X_0)), B, R^0)$. Therefore, a call to an external SMT solver is just an invocation of the function $\text{sat}$ in $\text{SAT}()$ in order to achieve the above functionality more efficiently and in a built-in way.

Given that the symbolic rewrite relation $\rightsquigarrow_{R^0}$ is encoded as a standard rewrite relation, symbolic search can be directly implemented in Maude by its search command. In particular, for terms $t, u^\circ$, constraints $\varphi_1, \varphi_2$, $F$ a variable of sort $\text{QFFormula}$, the following invocation solves the inductive reachability problem in Condition (2):

$$
\text{search } \langle t; \varphi_1 \rangle \rightarrow^* \langle u^\circ; F \rangle \text{ such that } \text{sat}(F \land \varphi_2).
$$

6 Analysis of the CASH algorithm

This section presents an example, developed jointly with Kyungmin Bae, of a real-time system beyond the scope of timed automata [2] that can be symbolically analyzed in the prototype tool integrating Maude and CVC3 described in Section 5. The analysis uses such a prototype to perform model checking based on rewriting modulo SMT. Some details are omitted; full details and the prototype tool can be found in [8].

The example involves the symbolic analysis of the CASH scheduling algorithm, developed by Caccamo, Buttazzo, and Sha [12], which attempts to maximize system performance while guaranteeing that critical tasks are executed in a timely manner. This is achieved by maintaining a queue of unused execution budgets that can be reused by other jobs to maximize processor utilization. CASH poses non-trivial modeling and analysis challenges because it contains an unbounded queue. Unbounded data types cannot be modeled in timed-automata formalisms, such as those of UPPAAL [20] or Kronos [37], which assume a finite discrete state.

The CASH algorithm was specified and analyzed in Real-Time Maude by explicit-state model checking in an earlier paper by Ölveczky and Caccamo [29], which showed that, under certain variations on both the assumptions and the design of the protocol, it could miss deadlines. But explicit-state model checking has intrinsic limitations which the new analysis by rewriting modulo SMT presented below overcomes. The CASH algorithm is parametrized by: (i) the number $N$ of servers in the system, and (ii) the values of a maximum budget $b_i$ and period $p_i$, for each server $1 \leq i \leq N$. Even if $N$ is fixed, there are infinitely many initial states for $N$ servers, since the maximum budgets $b_i$ and periods $p_i$ range over the natural
numbers. Therefore, explicit state model checking cannot perform a full analysis. If a counterexample for \( N \) servers exists, it may be found by explicit-state model checking for some chosen initial states, as done in [30], but it could be missed if the wrong initial states are chosen.

Rewriting modulo SMT is useful for symbolically analyzing infinite-state systems like CASH. Infinite sets of states are symbolically described by terms which may involve user-definable data structures such as queues, but whose only variables range over decidable types for which an SMT solving procedure is available. For the CASH algorithm, the built-in data types used are the Booleans (sort \( \text{iBool} \)) and the integers (sort \( \text{iInt} \)). Integer built-in terms are used to model discrete time. Boolean built-in terms are used to impose constraints on integers.

A symbolic state is a pair \( \{ \text{iB}, \text{Cnf} \} \) of sort \( \text{Sys} \) consisting of a Boolean constraint \( \text{iB} \), with \text{and} denoted \( ^\wedge \), and a multiset configuration of objects \( \text{Cnf} \), with mutiset union denoted by juxtaposition, where each object is a record like-structure with an object identifier, a class name, and a set of attribute-value pairs. Each object configuration there is a global object (of class \( \text{global} \)) that models the time of the system (with attribute name \( \text{time} \)), the priority queue (with attribute name \( \text{cq} \)), the availability (with attribute name \( \text{available} \)), and a deadline missed flag (with attribute name \( \text{deadline-miss} \)). A configuration can also contain any number of server objects (of class \( \text{server} \)). Each server object models the maximum budget (the maximum time within which a given job will be finished, with attribute name \( \text{maxBudget} \)), period (with attribute name \( \text{period} \)), internal state (with attribute name \( \text{state} \)), time executed (with attribute name \( \text{timeExecuted} \)), budget time used (with attribute name \( \text{usedOfBudget} \)), and time to deadline (with attribute name \( \text{timeToDeadline} \)). The symbolic transitions of CASH are specified by 14 conditional rewrite rules whose conditions specify constraints solvable by the SMT decision procedure. For example, rule \([\text{deadlineMiss}]\) below models the detection of a deadline miss for a server with nonzero maximum budget.

```
vars AtSG AtS : AttributeSet .
var iB : iBool .
var Cnf : Configuration .
vars iT iT' iNZT : iInt .
var St : ServerState .
vars G S : Oid .
var B : Bool .
crl [\text{deadlineMiss}] :
  \{ iB, < G : \text{global} | \text{dead-miss} |\rightarrow B, AtSG > 
    < S : \text{server} | \text{state} |\rightarrow St, usedOfBudget |\rightarrow iT, 
    \text{timeToDeadline} |\rightarrow iT', 
    \text{maxBudget} |\rightarrow iNZT, AtS > Cnf \}
=> \{ iB ^ iT >= c(0) ^ iNZT > c(0) ^ iT' > c(0) ^ iNZT > iT + iT', 
    < G : \text{global} | \text{dead-miss} |\rightarrow true, AtSG > 
    < S : \text{server} | \text{state} |\rightarrow St, usedOfBudget |\rightarrow iT, 
    \text{timeToDeadline} |\rightarrow iT', 
```

14
maxBudget |-> iNZT, AtS > Cnf }
if St /= idle /\ check-sat(iB ^ iT >= c(0) ^
  iNZT > c(0) ^ iT’ > c(0) ^
iNZT > iT + iT’) .

That is, the protocol misses a deadline for server S whenever the value of attribute
maxBudget exceeds the addition of values for usedOfBudget and timeToDeadline
(i.e., iNZT > iT + iT’), so that the allocated execution time cannot be exhausted
before the server’s deadline.

The goal is to verify symbolically the existence of missed deadlines of the CASH
algorithm for the infinite set of initial configurations containing two server objects
s0 and s1 with maximum budgets b0 and b1 and periods p0 and p1 as unspecified
natural numbers, and such that each server’s maximum budget is strictly smaller
than its period (i.e., 0 ≤ b0 < p0 ∧ 0 ≤ b1 < p1). This infinite set of initial states is
specified symbolically by the equational definition (not shown) of term symbinit.
Maude’s search command can then be used to symbolically check if there is a
reachable state for any ground instance of symbinit that misses the deadline:

search in SYMBOLIC-FAILURE : symbinit =>*
  { iB:iBool, Cnf:Configuration < g : global |
    AtS:AttributeSet, deadline-miss |-> true > } .
Solution 1 (state 233)
states: 234 rewrites: 60517 in 2865ms cpu
(2865ms real) (21118 rewrites/second)
iB:iBool -->(i(0) <= c(0) ^
  i(1) <= c(0)) v i(0) <= c(0) + i(1) ^
...
Cnf:Configuration -->
< s1 : server | maxBudget |-> i(0), period |-> i(1),
  state |-> waiting, usedOfBudget |-> c(0),
  timeToDeadline |-> ((i(1) -- c(1)) -- c(1)),
  timeExecuted |-> c(0) >
< s2 : server | maxBudget |-> i(2), period |-> i(3),
  state |-> executing, usedOfBudget |-> c(2),
  timeToDeadline |-> ((i(3) -- c(1)) -- c(1)),
  timeExecuted |-> c(2) >
AtS:AttributeSet ---> time |-> c(2), cq |-> emptyQueue,
  available |-> false

A counterexample is found at (modeling) time two, after exploring 233 symbolic
states in less than 3 seconds. By using a satisfiability witness of the constraint iB
computed by the search command, a concrete counterexample is found by exploring
only 54 ground states. This result compares favorably, in both time and computa-
tional resources, with the ground counterexample found by explicit-state model
checking in [29], where more than 52,000 concrete states where explored before find-
ing a counterexample.
7 Related Work and Concluding Remarks

The idea of combining term rewriting/narrowing techniques and constrained data structures is an active area of research, specially since the advent of modern theorem provers with highly efficient decision procedures in the form of SMT solvers. The overall aim of these techniques is to advance applicability of methods in symbolic verification where the constraints are expressed in some logic that has an efficient decision procedure (see [28] for an overview). In particular, the work presented here has strong similarities with the narrowing-based symbolic analysis of rewrite theories initiated in [24] and extended in [7]. The main difference is the replacement of narrowing by SMT solving and the decidability advantages of SMT for constraint solving.

M. Ayala-Rincón [4] investigates, in the setting of many-sorted equational logic, the expressiveness of conditional equational systems whose conditions may use built-in predicates. This class of equational theories is important because the combination of equational and built-in premises yield a type of clauses which is more expressive than purely conditional equations. Rewriting notions like confluence, termination, and critical pairs are also investigated. S. Falke and D. Kapur [15] studied the problem of termination of rewriting with constrained built-ins. In particular, they extended the dependency pairs framework to handle termination of equational specifications with semantic data structures and evaluation strategies in the Maude functional sublanguage. The same authors used the idea of combining rewriting induction and linear arithmetic over constrained terms [16]. Their aim is to obtain equational decision procedures that can handle semantic data types represented by the constrained built-ins. H. Kirchner and C. Ringeissen proposed the notion of constrained rewriting and have used it by combining symbolic constraint solvers [19]. The main difference between their work and rewriting modulo SMT presented in this paper, is that the former uses narrowing for symbolic execution, both at the symbolic ‘pattern matching’ and the constraint solving levels. In contrast, rewriting modulo SMT solves the symbolic pattern matching task by rewriting while constraint solving is delegated to an SMT decision procedure. More generally, a difference common to [4, 15, 16, 19] is that all of those papers address symbolic reasoning for equational theorem proving purposes, but none of them addresses the kind of non-deterministic rewrite rules, which are needed for open system modeling.

This paper has presented rewrite theories modulo built-ins and has shown how they can be used for symbolically modeling and analyzing concurrent open systems, where non-deterministic values from the environment can be represented by built-in terms. Under reasonable assumptions, including decidability of $\mathcal{E}_0^+$, a rewrite theory modulo is executable by term rewriting modulo SMT. This feature makes it possible to use, for symbolic analysis, state-of-the-art tools already available for Maude, such as its space search commands, with no change whatsoever required to use such tools. We have proved that the symbolic rewrite relation is sound and complete with respect to its ground counterpart, have presented an overview of the prototype that offers support for rewriting modulo SMT in Maude, and have presented a case study on the symbolic analysis of the CASH scheduling algorithm illustrating the use of these techniques.

Future work on a mature implementation and on extending the idea of rewriting
modulo SMT with other symbolic constraint solving techniques such as narrowing modulo should be pursued. Also, the extension to symbolic LTL model checking, together with state space reduction techniques, should be investigated. The ideas presented here extend results in [32] and have been successfully applied to the symbolic analysis of NASA’s PLEXIL language to program open cyber-physical systems [32]. Future applications to PLEXIL and other languages should also be pursued.

References

Combining symbolic techniques such as: (i) SMT solving, (ii) rewriting modulo theories, and (iii) model checking can enable the analysis of infinite-state systems outside the scope of each such technique. This paper proposes rewriting modulo SMT as a new technique combining the powers of (i)-(iii) and ideally suited to model and analyze infinite-state open systems; that is, systems that interact with a non-deterministic environment. Such systems exhibit both internal non-determinism due to the system, and external non-determinism due to the environment. They are not amenable to finite-state model checking analysis because they typically are infinite-state. By being reducible to standard rewriting using reflective techniques, rewriting modulo SMT can both naturally model and analyze open systems without requiring any changes to rewriting-based reachability analysis techniques for closed systems. This is illustrated by the analysis of a real-time system beyond the scope of timed automata methods.
