THE VISUAL IMPAIRMENT INTRACRANIAL PRESSURE SYNDROME IN LONG DURATION U.S. ASTRONAUTS: EPIDEMIOLOGY AND PATHOPHYSIOLOGY

Lead Scientist, NASA VIIP Risk
Universities Space Research Association, Houston, TX,

Sensorimotor Workshop
NSBRI, Houston, TX
Thursday August 29, 2013.
Visual Impairment Intracranial Pressure Syndrome Signs

- **Hyperopic Shifts**
  - Up to +1.75 diopters

- **Choroidal Folds**
  - Parallel grooves in the posterior pole

- **Globe Flattening**

- **Optic Disc Edema (swelling)**

- **Altered Blood flow**
  - "cotton wool" spots

- **Increased Optic Nerve Sheath Diameter**

MRI Orbital Image showing globe flattening
VIIP Clinical Findings

- To date 15 U.S. ISS long-duration spaceflight astronauts have developed some or all of the following findings:
  - Hyperopic shift
  - Choroidal folds
  - Cotton wool spots
  - Optic Nerve Sheath Distention
  - Globe flattening
  - Edema of the Optic disc (papilledema)

- Signs of elevated intracranial pressure

- High postflight intracranial pressure in four crew members:
  - 15.4-21.3mmHg (Normal: 7-15mmHg) or,
  - 21-29 cmH2O, Normal: 9.5-20.4cmH2O
Initial Identification of the VIIP: Subjective Changes in Vision

• 50% of long-duration (ISS) mission astronauts report a subjective degradation in vision, primarily increasing *farsightedness*

• **Hyperopic shift**
  
  Decreased near visual acuity, distant vision intact

(1 mm decrease in axial length is equivalent to a 3 diaper hyperopic shift)
Pre to Post Flight Papilledema: A Clinical Sign of Raised Intracranial Pressure

Pre Flight
Fundoscopic images of the right and left optic disc.

Post Flight
Fundoscopic images of the right and left optic disc showing **Grade 3 edema right** and **Grade 1 edema left**.
In Flight B-scan Ultrasound
Because of a variable pressure-diameter relationship, the clinical relevance of this method relies on the demonstration of ongoing enlargement on serial US studies.

78 measures
\[ r = 0.71 \]
\[ p < 0.0001 \]
ISS Inflight Crew Ultrasound Imaging: Additional Signs of Raised Intracranial Pressure

1. Increased Optic Nerve Sheath Diameter

2. Posterior Globe Flattening

3. Raised Optic Disc
Choroidal Folds

Thickening of the choroid secondary to venous blood engorgement from uG fluid shift
### VIIP Clinical Practice Guideline

Jugular Vein Pressure & ICP Increases in Simulated Microgravity

- Jugular bulb pressure approximates dural sinus pressure
- Jugular vein pressure measured in 7 animals during 4.5s free drop
- Loss of hydrostatic pressure gradient increased $JVP_{\Delta}$ 1.3mmHg
  - i.e. loss of hydrostatic assisted venous drainage
- Similar study, ICP increased in 5 rats from 4.8 to 7.3 mmHg =52% increase in ICP
- Factors that may further raise ICP:
  - Complete cephalad fluid shift, Increased CO2

CO₂ Levels on ISS

- CO₂ is an extremely potent vasodilator
  - Every 1mmHg increase PaCO₂=4% increase in dilation

- CO₂ mission average=3.56mmHg (0.33%)
  - 10x normal sea level atmospheric: 0.0314%
  - Average Peak CO₂=8.32mmHg (0.7%) (20x)

- CO₂ may cause increased CSF production due to increased flux of HCO₃⁻ across choroid plexus & accompanying H₂O

Adapted from Alperin et al. Radiology, 2000
Increased BP with Elevated CO2 Causing Decreased Compliance

Data mining - Contributions of CO₂ to the VIIP syndrome

- **PI:** TBD

- **Aims:** This retrospective data mining effort will evaluate the in-flight CO₂ levels during flight with the time course of identified visual changes experienced by crew members to determine if increased CO₂ levels could be a contributing factor to the VIIP syndrome.

- Zwart et al. 2012 found a difference in CO₂ concentrations between cases and non-cases:
  
  - In-flight cabin CO₂ concentrations were higher (P < 0.05) for OC+ (N=5) than OC- astronauts (N=15).

A Working Model: Potential Interaction of the 
CNS, Vascular, & Ocular System in the VIIP

Adapted from Rekate
Supplemental O2 as a Treatment Option

- As the arterial tension of CO2 rises, CBF increases, when it is reduced vasoconstriction is induced.
- Hyperventilation can lead to a mean reduction in intracranial pressure of about 50% within 2-30 minutes.

Correlation of ONSD & Visual Field Deficit

- 20 patients with IIH (mean age=47) papilledema grade 1.1 (range 0-4), 20 controls
- CSF pressure=260-320mmH2O, Mean duration disease=7.65 years
- Perimetric defects in 70% of eyes (28/40)
- Deficit associated with papilledema grade

**MD:** Average deviation from age matched controls

![Graph showing correlation between optic nerve diameter and mean threshold](image)

- Left eye
- \( r = -0.75 \) (n = 10)
- \( p = 0.01 \)

**PSD:** Measure of visual field irregularities

![Graph showing correlation between optic nerve diameter and pattern standard deviation](image)

- Left eye
- \( r = 0.73 \) (n = 10)
- \( p = 0.02 \)

Page No. 52

- 24 IIH patients, symptoms present 1-30 months
- Median CSFp=25mm Hg (range 8-45), all had papilledema initially
- Followed for 49 months, treated with Diamox and diuretics 6-18 months
- Patients who regained normal disc (50%) had shorter duration of disease (median=4 months) vs those who developed chronic changes (median=12 months)
- Visual field testing not conducted

Blind Spot Enlargement Following Papilledema

**Graph:**
- Normal Blind Spot Area
- Chronic Disc Changes
- Papilledema grade Δ 2.25 to 0.9
- Regained normal disc appearance
- Papilledema grade Δ 1.9 to 0

(Months 0-14, Median 49)
**Visual Loss Associated with Papilledema Grade**

- 9 IIH patients (mean age=31.8) with asymmetric papilledema 2+ grade diff.
  - High grade=3 (2-5) vs Low grade=1 (0-2)
- Mean CSFp=347.2 mm H2O
- Visual loss most prominent in eye with higher grade papilledema
- High grade papilledema should be regarded as a risk factor for visual loss

---

### The Visual Island

- Depression of the visual island with increasing papilledema grade

- **Profile Perimetry**
Mild Papilledema and Visual Field Loss

- N=22, mean age=40, recent diagnosis of IIH
- Mild papilledema, mean= Frisen 2 (range 1-3)
- Mean CSFp=35cmH2O (range 25.5-45)
- 1 Year follow-up:
  - Perimetry: 66% normal VF, 18% enlargement blind spot, 16% irreversible field loss
  - OCT: 10 RNFL thinner than normal (3 visual field constriction, 3 inferonasal defects, 1 had a scotoma)

- RNFL swelling and attrition may occur simultaneously
- Perimetry needed with OCT, since OCT cannot distinguish between decreased swelling vs axonal loss

*Both OCT and perimetry required for F/U*

- 23 IIH patients, mean age 33.8, 23 controls
- Mean follow-up in patients with regression of papilledema=27 months
- 8/13 (63%) regressive papilledema group had mild-moderate concentric visual field damage-superior and inferior regions
- Patients with papilledema, only 1/10 detectable visual field loss
- Data show significant reduction RNFL as a sign of axon loss in patients with apparently treated papilledema
- Minor loss of axons will be masked by structure of retina, with overlapping receptive fields. Thus, 40% of RNFL may be lost before occurrence of visual field damage
Microgravity Dose Response for the VIIP?

- N=27 Astronauts, mean time to MR imaging was 606 days +/- 822
- 18 group 1 astronauts underwent imaging more than 100 days after flight
- Consistently higher percentage of findings for group with greater microgravity exposure, and increased severity of findings.
