Characterization of Commercial Li-ion Cells in Pouch Format

Judith Jeevarajan, Ph.D.
NASA-JSC, Houston, TX
April 2014
The 2014 Space Power Workshop
Background

• Commercial off-the-shelf (COTS) li-ion cells are frequently subjected to a standard set of tests to determine their performance and safety in order to add them to a database that allows users at NASA, specifically at Johnson Space Center, to choose cell designs for different applications.

• In recent years, Li-ion polymer cells in pouch format are used increasingly in portable equipment applications and are commonly being referred to as lithium polymer cells, although these cells are not of the true polymer types.

• Several Li-ion polymer or pouch cells have been tested at NASA-JSC in the past 15 years. Cells of this type have developed from being low rate (Ultralife, 1998) to medium rates (Valence, Samsung, Kokam, etc. ~2005) and then on to high energy and high rates (~2010-).

• Testing of these li-ion polymer cells have shown that long term storage as well as vacuum exposures cause swelling of the pouch; there is also a variance in their safety characteristics under off-nominal conditions.

• Recent test programs at NASA-JSC have focused on testing the li-ion polymer cells for their safety as well as their performance under different rates and temperatures, and in addition to this, under vacuum and reduced pressure conditions.

• 100% of flight batteries including button cells undergo vacuum leak checks before they are flown for NASA space applications. The lack of pouch li-ion cells to vacuum conditions may require a change in test methods for batteries that use this cell design. Use of reduced pressure has been an option.

• Hence this test program was started to determine the tolerance of these cells to vacuum as well as reduced pressure environments.

• The most recent tests included cells of the following types:
  SKC 15 Ah (high-rate capability)
  Tenergy 6 Ah (medium rate medium energy density)
  Altairnano 13 Ah (nanotitanate anode with high rate capability)
  Wanma 5 Ah (medium rate medium energy density)
  iPad Battery ~4.0 Ah
  GMB 3.9 Ah
  Kokam 5.0 Ah

Wanma 5 Ah Li-ion Cell with Cycling Under Low Pressure or Vacuum Environments and Storage at Ambient

Vacuum exposure reduces performance tremendously
Compared to low pressure environments

J. Jeevarajan, Ph.D. / NASA-JSC
iPad Li-ion Pouch Cells Under Vacuum and Reduced Pressure Conditions

Vacuum exposure for 6 hours at 0.1 psi
1.94 Ah retained after vac exposure;
original capacity was 2.66 Ah (27% capacity loss);
No swelling was observed post-vacuum.

Low Pressure exposure for 6 hours at 9 +/- 0.5 psi.
1.91 Ah retained after low pressure exposure;
original capacity was 2.95 Ah (35 % capacity loss);
No swelling was observed post-vacuum.

Analysis of Pouch Materials from the Different Manufacturers
Summary

• The li-ion pouch design cells exhibit similar behavior under off-nominal conditions as those in metal cans that do not have the internal safety devices.
  – Safety should be well characterized before batteries are designed.
• Some of the li-ion pouch cell designs studied in this program reacted most violently to overcharge conditions at the medium rates but were tolerant to overcharge at very low rates.
• Some pouch cell designs have higher tolerance to vacuum exposures than some others.
  – A comparison of the pouch material itself does not show a correlation between this tolerance and the number of layers or composition of the pouch indicating that this is a property of the electrode stack design inside the pouch.
• Reduced pressure (8 to 10 psi) test environments show that the extent of capacity degradation under reduced pressure environments is much less than that observed under vacuum conditions.
• Lithium-ion Pouch format cells are not necessarily true polymer cells
