The dipole moment changes for events A, B, C and D. For the first three events, the electrostatic field change was negative. The closest NBE observed was located 2.8 km from the nearest station. During two years of NBE observations, 9100 positive NBE were observed. In contrast, only 6900 negative NBE were observed. The positive NBE transferred 0.5 C of charge at an average current of 21 kA. On the other hand, negative NBE had a negative starting radiation field change of 0.15 and 0.6 C-km. The discharges were located 9.7, 8.9, 7.7 and 8.3 km from the near station, respectively. Durations for events A, B, C and D were 24 microseconds, 44 microseconds, 92 microseconds, and 240 microseconds, respectively. There was a reversal distance of 10 km. The near measurement station measures only the radiation field, this zero crossing forms is crossing back through zero (Figure 1e). Since distant stations located 2.8, 6.7, 9.9 and 14.5 km from the near station, the reversal distance. This NBE had an altitude of 8.3 km above the reversal distance. The dipole moment change of the field-change instrument. Figure 2 shows the waveforms for these events, labeled A, B, C and D. For the current to be transferred, current and discharge length are estimated to be 2.8, 9.9 and 14.5 km from the near station. Durations for events A, B, C and D were 24 microseconds, 44 microseconds, 92 microseconds, and 240 microseconds, respectively. There was a reversal distance of 10 km. The electrostatic field change was negative. The closest NBE observed was located 2.8 km from the nearest station. During two years of NBE observations, 9100 positive NBE were observed. What is a narrow bipolar event (NBE)?

NBEs are compact (< 2 km), powerful (> 10 kW in VHF), and impulsive (~10 μs) electrical discharges in thunderstorms, also known as compact intracloud discharges (CID) [e.g., Smith et al. 1999].

Can be either positive or negative polarity (Wu et al. 2012), and have distinctive broadband waveform signatures (Eack 2004) sometimes confused for +CGs in the past by NLDN and other networks (Tessendorf et al. 2007).

NBEs are related to lightning but are likely optically “dark” (Jacobson et al. 2013).

As revealed by VHF sensors (both satellite and ground):
- The most powerful lightning-related VHF sources observed (Jacobson et al. 2013)
- Tend to occur at the beginning of intracloud discharges (Rison et al. 1999)
- Difficult to estimate altitude properly due to receiver saturation (Thomas et al. 2001)
How do NBEs relate to thunderstorm structure and evolution?

Good question! This is still open for exploration.

What we know to date

- Tend to occur near strong (~40-dBZ) cores (e.g., Smith et al. 1999)
- Tend to occur at high altitudes (> 8 km; Wu et al. 2012)
- Correlated to cloud-to-ground (CG) flash rate (Suszcynsky and Heavner 2003)
- Correlated to 30-dBZ heights (Wiens et al. 2008)
- Certain individual storms can produce very high NBE rates (Wiens et al. 2008)

Outstanding issues

- What is distinctively different about storms that produce many NBEs?
- Case studies needed of NBE occurrence related to total flash rate and storm evolution
Data and Methodology

North Alabama Lightning Mapping Array (NALMA)
National Lightning Detection Network (NLDN)
National 3-D Radar Reflectivity Mosaics (NMQ)

McCaul LMA flash-counting methodology (McCaul et al. 2005)

No waveform data, so instead use concept of “NBE candidates”

• NALMA flashes containing 40+ dBW source (DB40)
• Flashes containing 40+ dBW initial source (NB40)
• Flashes containing 50+ dBW source (DB50)
• Flashes containing 50+ dBW initial source (NB50)

DB40 is least-stringent category, NB50 the most stringent

Modest altitude criteria to filter out very poor solutions
Notable NALMA NBE candidate cases (2002-2012)

Data plotted as ~6-h cases

The two ~6-h periods on 4 August 2011 are by far the biggest NBE candidate producers, by any metric.
4 August 2011 Svr Wx Reports (thru 12 UTC)
NALMA NBE Candidates vs. Max Flash Rate Densities (2002-2012)

**n40dbw vs. maxFRD**

Flash contains 40 dBW source anywhere (DB40)

Two ~6-h periods on 4 August 2011

**nnbe50 vs. maxFRD**

Flash contains 50 dBW as initial source (NB50)

Standout NBE candidate cases are middle of the road in terms of max flash rates
Equilibrium Level ~14.8 km!
4 August 2011 NMQ composite reflectivity (contours) and 40 dBW flashes (X) 
100-km and 200-km NALMA Range Rings (dashed circles)

Cell mergers appear to be associated with enhanced NBE candidate activity
**Bulk Regional Time Series**
- Includes all observations within 200 km range of NALMA center
- Superficial comparison suggests good correlations among 30/40 dBZ volumes and various flash parameters, including NBES
Bulk Spearman’s Rank Correlations

**Echo volumes vs. TFR/CGs**

- NALMA Range/DE effects
- NBE candidates best correlated to 40-dBZ echo volumes.
- DB40 category highest correlations
- Higher NBE correlations to +CGs interesting (Tessendorf et al. 2007)

**Echo volumes vs. NBE candidates**

**NBE candidates vs. TFR/CGs**

DB40/NB50 correlation = 0.52
Basic idea – Identify and track features in radar data, link lightning and other observations to those features using simple temporal/spatial criteria for later statistical or case study analysis.

Lang and Rutledge (2011)

CSU Lightning, Environment, Aerosols, and Radar (CLEAR) statistical framework

Fuchs et al. (2013) tracking
Twin thresholds - 30 & 40 dBZ
2-D median filter (4-km)

NALMA flashes/sources
NLDN Flashes
NBE Candidates
Examination of Merger
Tracks 7 & 30

LMA total flash rate \([x10 \text{ (5 min}^{-1})]\)
NLDN CG flash rate \((5 \text{ min}^{-1})\)
NMQ Volume 30 dBZ \((x100 \text{ km}^3)\)
NMQ Volume 40 dBZ \((x100 \text{ km}^3)\)

40 dBW sources \((5 \text{ min}^{-1})\)
50 dBW initial sources \((5 \text{ min}^{-1})\)

DB40 well correlated to storm metrics during two-hour analysis window

NB50 somewhat correlated to reflectivities, no statistically significant correlation with TFR, CGs
Vertical analysis
Tracks 7 & 30

LMA total flash rate [$\times 10 \text{ (5 min}^{-1})$]
NLDN CG flash rate (5 min$^{-1}$)

NMQ Volume 20 dBZ (km$^3$)
NMQ Volume 30 dBZ ($\div 2$ km$^3$)
NMQ Volume 40 dBZ ($\div 4$ km$^3$)
Solid: $T < 0 \text{ C}$
Dash: $T < -20 \text{ C}$
Dot: $T < -40 \text{ C}$

40 dBW sources (5 min$^{-1}$)
50 dBW init. sources [$\div 10 \text{ (5 min}^{-1})$]

DB40, TFR, and CGs highly correlated to vertical intensity
NB50 loosely correlated at best
**NBE candidate burst cell**

- Ground zero for merger of larger storms
- Mid-strength reflectivity structure
- Comparable in terms of total flash production
Conclusions and Future Work

NBE candidates occurred within strong convection
- But not always the strongest!
- DB40 best correlation to storm metrics (influence of TFR?)
- NB50 worst correlation (Sampling issues?)
  - Low to no correlation with other lightning
  - Some statistically significant correlation to radar metrics
- NBE candidate burst associated with cell merger

*Intense convection a necessary, but not sufficient, condition for NBE production?*
- Results consistent with NBEs requiring an additional trigger
- Effect of solar proton storm on 4 August 2011?

**To Do**
- Further analysis of this case – additional time periods
- Examine other cases (e.g., 2\textsuperscript{nd} most NBEs - 7/31/2012)
- Statistics for NBE/No-NBE storms
