Outline

• Motivation
• Superconducting Magnetic Sensor
  • SQUID
  • SQUID Arrays
  • Experimental Data
  • Fabrication Aspects
  • Cryogenic Aspects
• Comparison to conventional technologies
• Conclusion
Motivation: Sensitivity, Size, Bandwidth

- Conventional semiconductor electric field detection limited at about $kT \approx 10^{-22}$ J
- Existing communication and direction finding techniques require multiple antennas with sizes that are a significant fraction of the incident wavelength, and that are separated by a distance comparable to the incident wavelength. For frequencies of 3 MHz and 300 MHz the wavelengths are 100 and 1 meter respectively.

- Goals:
  - Decreasing antenna size
  - Increasing bandwidth
  - Increasing sensitivity
Use Magnetic Antenna

- Use magnetic instead of electric field detection to take advantage of highly sensitive Superconducting Quantum Interference Device (SQUID) arrays.
  - Proven and being used in medical and physics research, geology, etc.
- SQUIDs have a typical energy sensitivity per unit bandwidth of about $10^6$ h or $\approx 10^{-28}$ J.
- Conventional semiconductor electric field detection threshold of $\sim kT \approx 10^{-22}$ J.
SQUID – magnetic field sensor

Superconducting Quantum Interference Device (SQUID) invented in 1964 (50 years ago), R. Jaklevic, J. Lambe, J. Mercereau, A. Silver (US)

Can measure fields as low as 5 aT (5×10⁻¹⁸ T) (a few days of averaged measurements)

$S_B = 3 \text{ fT} \cdot \text{Hz}^{-\frac{1}{2}}$

$\Phi_0 = \frac{h}{2e} = 2.07 \times 10^{-15} \text{ mV ps (Wb)}$
Bi-SQUID – linearized SQUID

- Non-linear inductance of additional junction ($I_{c3}$) linearizes the SQUID response
Array of SQUIDs

- In a current-biased series array the voltage signal increases with the number of connected SQUIDs in the array (N), but the noise only increases as $N^{1/2}$. Therefore as N becomes larger the signal-to-noise ratio increases as $N^{1/2}$.

- In series-parallel SQIFs,
  - (i) increase output voltage and dynamic range;
  - (ii) control response linearity and output impedance;
  - (iii) improve sensitivity to weak signals;
  - (iv) make response robust to variation in junction critical currents.
Non-uniform SQUID Array - SQIF

SQIF: Superconducting Quantum Interference Filter - quantum interferometer with non-equal loop geometry

SQIF was invented in 2001 by N. Schopohl, et al. (Germany)
Why SQUID Array

An analogy to explain SQIF operation (in terms of sensitivity):

The SNR output of a discrete Fourier transform, which basically integrates a time series, scales as the square root of N, where N is the number of points processed in the FFT, i.e., the signal magnitude scales as N but the noise standard deviation scales as the square root of N, hence SNR is proportional to the square root of N - processing gain.

The SQIF processes N signals in parallel via N SQUID loops. For an ergodic process (statistics averaged over time are equivalent to statistics averaged over space), the result is the same: SNR scales as the square root of N. This leads to the SQIF’s ability to theoretically achieve a noise floor that approaches zero.
SQIF-based Receive Antenna

Can be cryogenic superconducting circuits or room-temperature conventional electronics or both (hybrid)

Cryogenic superconducting circuits

Cryogenic or room-temperature depending on applications
SQUID Serial Array

control line

Bi-SQUID 2D Array Samples

Fabricated 5 mm x 5 mm chips using HYPRES Nb-AlOx-Nb Josephson junction process. Diamond-double bi-SQUID arrays.

two serially connected 2D arrays (2 x 43 x 85) arrays with 7310 cells

a single 7820-cell (92 x 85) 2D array
Array Noise Improvement

Comparison of the measured flux noise spectral densities for the 20-, 200- and 1000-cell arrays. It is evident that noise is getting reduced for 1000-cell array compared to 20-cell array as ~ $N^{1/2}$ or ~7 times as theoretically expected.
Array Linearity Improvement

Measured two-tone (158 MHz and 162 MHz) response for (left) 200-cell and (right) 1000-cell serial bi-SQUID array at dc bias level placing operation point at a midpoint of anti-peak SQIF slope with 5 dB/div
Measured output power level of a 1000-cell serial bi-SQUID arrays at three dc bias levels placing the array operation point at 1 – near the tip of the anti-peak, 2 – a midpoint of the anti-peak slope (optimum), 3 – outside of the anti-peak (saturation region)
Superconductor Circuit Fabrication

• Two types of Superconductor Materials
  • **Low Temperature Superconductors** (**LTS**)  
    • for 4K operation  
    • Industrial-grade Nb-AlOx-Nb Josephson junctions  
    • Available commercially (HYPRES, AIST (Japan), IPHT (Germany))
  
  • **High Temperature Superconductors** (**HTS**)  
    • For ~70 K operation  
    • Research grade YBCO Josephson junctions  
    • Available from research labs (UCSD (San Diego), CSIRO (Australia), etc.)
LTS Fabrication Process
Nb-AlOx-Nb junctions for 4 K operation

HYPRES Fabrication Process

- High $J_c$ (20 kA/cm$^2$) with MoN resistors – *under development*
  - RSFQ (Digital & Mixed-signal)
- Medium $J_c$ (1 kA/cm$^2$ and 4.5 kA/cm$^2$) with Mo resistors
  - RSFQ (Digital & Mixed-signal)
- Low $J_c$ (30 A/cm$^2$) with Al, Mo, or Ti/PdAu resistors
  - SQUID applications
  - 1 V and 10 V Voltage Standard
  - QC circuits for mK operation

~6 mask releases per year (current number is 350)
~400 chips per wafer

1x1 cm$^2$ die
150 mm dia.
5x5 mm$^2$ die

Cryocooling for 4 K operation

- Weight: 7.2 kg (for coldhead only)
- Input Voltage: 18-28 VDC
- Maximum Input Power: 1.5 kW (compressor power)
- Cooldown Time (300 to 4K): 150 min (unloaded).
- Cooling Capacity: 0.2W @4.2K and 3-5W@45K

HTS Fabrication Process
YBCO junctions for ~70 K operation

Univ. California San Diego (UCSD) fabrication process

Based on Ion Damage Josephson Junction (IDJJ) fabrication technique
Cryocooling for 70-77 K operation

- Weight: 715 g
- Input Voltage: 18-28 VDC
- Steady State Input Power (1000mW @77K): 20W Typ. @23°C
- Maximum Input Power: 45W
- Ambient Temperature Range
  - Operational: -40°C...+71°C
  - Non-Operational: -56°C...+85°C
- Cooldown Time (500J @23°C): 4 min. Typ.
- Cooling Capacity: 1W @77K @71°C
- MTTF > 15,000 Hours (Goal)
- Meets Environmental Conditions per MIL-STD-810

Semiconductor Receiver versus SQIF Receiver (E vs. B)

SQUIDs can detect magnetic fields lower than one flux quantum $h/(2e) \approx 10^{-15}$ Wb, 10$^{-18}$ Wb reported in the literature.

**Conventional Receiver**
Mars link at 64 MBPS

- EIRP = 84 dBW ($\approx 2.5 \times 10^8$ W)
  - Assumes 100 W TWT, 12 m aperture
  - Range = 3.7X10$^8$ km
- Power density at receiver $\approx 2.8 \times 10^{-16}$ W/m$^2$
  - Electric Field $\approx 4.6 \times 10^{-7}$ V/m
  - Displacement flux density $\approx 10^{-18}$ C/m$^2$
- Receive Antenna Aperture
  - QPSK, Block Turbo Code, 3 dB margin
  - Required $E_b/N_0 = 4.6$ dB

  Aperture size 72 meters

**SQIF Superconducting Receiver**
Mars link at 64 MBPS

- EIRP = 84 dBW ($\approx 2.5 \times 10^8$ W)
  - Assumes 100 W TWT, 12 m aperture
  - Range = 3.7X10$^8$ km
- Power density at receiver $\approx 2.8 \times 10^{-16}$ W/m$^2$
  - Electric Field $\approx 4.6 \times 10^{-7}$ V/m
  - Displacement flux density $\approx 10^{-18}$ C/m$^2$
  - Magnetic Field $\approx 10^{-9}$ A/m
  - Magnetic flux density $\approx 10^{-15}$ Wb/m$^2$
- Receive Antenna Aperture
  - Flux Concentrator
  - Mechanical refrigerator at 4K

WFB: Frequency agile antennas and sensors using advanced control materials

IMS2014, Tampa, 1-6 June, 2014
Conclusions

- SQUID arrays have the potential to detect extremely weak magnetic fields to enable a new type of signal detection processing
- Can potentially lead to the development of antenna with quantum-limited sensitivity
- Electrically small broadband communication or direction finding system with high sensitivity, dynamic range, linearity, dynamic programmability, high angular accuracy
Backup
Measured Noise

\( S_{\phi_0}^{1/2} (f, \Omega) = \frac{S_f(f)}{2L} \), where \( f \) is frequency, \( L \) – inductance of bi-SQUID calculated from the measured separately, \( \Delta l_c \) modulation of IV curve defined as \( L = \phi_0 / 2 \Delta l_c \). Noise temperature is defined as \( T_N = \pi f \phi(f)/k_B \), where \( k_B \) is Boltzmann’s constant.
RF Coupling to SQIF array

\[ B(t) = B_0 + B_{rf}(t) \]

RF-signals modulate magnetic flux threading loop areas

→ copy of signal transferred into beat pattern of high frequency Josephson voltage output \( V(t) \)

Electrically small multi-loop antenna based on direct reception of magnetic field by individual loops
Josephson Junction

**Active component (switch) in superconductor electronics**

Below critical current “I<sub>c</sub”

\[
I < I_c
\]

Current flows through JJ at \( V = 0 \)

\[
I = I_c \sin(\phi)
\]

\( I > I_c \)

\( V \neq 0 \), and JJ passes magnetic flux through at rate \( \dot{\phi} \cdot \)

\[
\dot{\phi} = \Phi_0 / V_c
\]

**Typical Critical Current:**

\( I_c \sim 0.1 \text{ mA} \)

**Time constant:**

\( \tau \sim 1 \text{ ps (3-\text{um process})} \)

\( \tau \sim 0.1 \text{ ps (0.2-\text{um process})} \)
