  - Proposed Terrestrial Link Experiment

- Conclusions
Motivation
Motivation

- As a result of spectrum crowding and the need for wideband, high data rate space communications systems becomes increasingly problematic within the confines of currently utilized spectrum allocations, a typical approach is to move to higher frequencies where these limitations are not yet realized.

- Two communications architectures hoping to achieve multi-Gbps data rates are being investigated concomitantly by NASA, via the next generation Space Based Relay (SBR), and by AFRL, via the future military satellite communications (MILSATCOM) system, for the potential use of V/W-band space-earth links (NASA: 74-84 GHz, AFRL: 71-76/81-86 GHz).

- However, several issues related to propagation through the Earth’s atmosphere must be better understood before reliable communications systems can be designed at these frequencies. These issues include:
  - gaseous absorption, cloud attenuation (passive radiometry)
  - rain attenuation, scattering, scintillation, and signal depolarization (active beacon)
Absorption Spectra of the Atmosphere

Sea level specific attenuation spectra induced by the atmosphere as a function of frequency due to atmospheric gases and various rain rates [2].

Current operational frequency band (Ka)

Frequency band of interest to NASA/DoD
Motivation (continuation)

- Ideally, a space-based beacon should be employed to characterize the full propagation path, but, in the absence of such an opportunity, a terrestrial link can provide valuable information which can be used to enhance passive radiometric measurements.

- In this paper, preliminary results of gaseous and cloud attenuation estimates in the V/W-band derived from a microwave profiling radiometer deployed at White Sands, NM, is presented as a first-order estimate of V/W-band communications system performance.

**Could potentially characterize if transmitter placed above cloud layer**

Appears to be lack of terrestrial propagation data in the 70/80 GHz region of spectrum…
A Radiometrics MP-3000A Temperature, Humidity, and Liquid Profiler has been deployed at White Sands, NM, since September 1, 2012.

From the 35 channel radiometric measurements and derived atmospheric profiles, estimates of the gaseous and cloud attenuation in the V/W-band can be made using existing models.
The Cumulative Distribution Function (CDF) of losses due to gaseous and cloud attenuation for six months of data collection in White Sands, NM, is shown in Figure 2.

Radiometric data is for clear sky and cloud conditions only. Rain events were removed from data for CDF analysis.

**Observations:**

- Attenuation due to clouds can approach values in excess of 20 dB, which will limit system availability even without the presence of rain.
- Cloud attenuation at V/W-band will play a significant role in future V/W-band communications system design and will require mitigation techniques (e.g., site diversity).

Figure 2. CDF of estimated total path attenuation at 74 and 84 GHz derived from radiometer data and models.
Goals:

• To collect preliminary propagation data to better define satellite-based beacon system experiment and obtain first order estimates of atmospheric effects

• To characterize wide bandwidth (> 1GHz) phase dispersion effects due to atmospheric turbulence
Proposed Terrestrial Link Experiment (Cont.)

- From a mountain top position, a moderate elevation angle can be achieved along a slant path which can be used to characterize rain attenuation and scattering/depolarization effects.
- Dual frequency K (20.2 GHz) and W (80.8 GHz) band measurement will provide information on a scaling factor which can exploit existing K-band attenuation statistics to derive long term W-band statistics [10].

Cross-polarization isolation >25 dB at the transmitter and receiver is required to effectively measure any depolarization effects, as this is typical levels induced by atmospheric effects.

Dynamic range >50 dB is required to characterize W-band attenuation statistics >99.9% of time.

CDF of Rain Attenuation Losses Predicted From ITU-R P.618-10 Model [11]
Proposed Terrestrial Link Experiment (Cont.)

Transmitter Block Diagram

- Dual polarization coherent transmit
- Coherent 20/80 GHz frequencies for deep rain fade measurements

Receiver Block Diagram

- Dual polarization coherent receive for amplitude/phase decoherence measurement

Note: All LO’s share common 10 MHz reference
Conclusions

- For six months, radiometer data have been collected at White Sands, NM, which have provided estimates of gaseous and cloud attenuation statistics in the V/W-band, indicating significant challenges exist even for non-rainy conditions.

- Full characterization of V/W-band link performance requires the additional characterization of the effects of rain attenuation for space-earth communications systems to be designed reliably.

- Through the conduction of the terrestrial link experiment, critical first-order information on rain attenuation, scintillation, depolarization, and dispersion at V/W-band can be gathered without the need for a costly space-based beacon source.

- A dedicated measurement campaign for a minimum of 5 years is required to develop models for system performance at the New Mexico site.
