SINDA-FLUINT STRATIFIED TANK MODELING FOR CRYOGENIC PROPELLANT TANKS

Barbara Sakowski
NASA Glenn Research Center
Customization for Cryogenic Tank Analysis

- A general purpose SINDA/FLUINT (S/F) stratified tank model was created to simulate self-pressurization and axial jet TVS.
- Stratified layers in the vapor and liquid are modeled using S/F lumps.
- The stratified tank model was constructed to permit incorporating the following additional features:
  - Multiple or singular lumps in the liquid and vapor regions of the tank
  - Real gases (also mixtures) and compressible liquids
  - Venting, pressurizing, and draining
  - Condensation and evaporation/boiling
  - Wall heat transfer
  - Elliptical, cylindrical, and spherical tank geometries
Customization for Cryogenic Tank Analysis

• Extensive user logic is used to allow detailed tailoring – Don’t have to rebuilt everything from scratch!!

• Most code input for a specific case is done through the Registers Data Block:
  – Lump volumes are determined through user input:
    • Geometric tank dimensions (height, width, etc)
    • Liquid level could be input as either a volume percentage of fill level or actual liquid level height
1. The number of lumps in the vapor region need not be the same as the number of lumps in the liquid region.

2. The number of wall nodes in the vapor region need not be the same as the number of wall nodes in the liquid region.

3. Number of Wall Vapor Nodes = 3

4. Number of Vapor Lumps = 3 (Equal Volume)

5. Liquid level input as volume percentage of fill level or actual liquid level height.

6. Number of Wall Liquid Nodes = 3

7. Number of Liquid Lumps = 4 (Equal Volume)

8. LUMP VOLUMES:
   - Initial values (guesses) required
   - Extensive logic determines equal volume distribution

Fig 1: Stratified Tank Setup
SINDA/FLUINT Stratified Tank Setup

• Initialization of wall node volumes:
  – Determined by the number of nodes input for the vapor wall and liquid wall regions
  – Wall node volumes are not uniform values in the vapor region or liquid region
  – Wall node volumes correspond to “equal” fluid volumes in the vapor or liquid region
Volume Flow Rate Connectors (VFRSETs) are placed between the layered lumps in each region to equalize volumes:

- Used during venting, draining
- Used during mass transfer of evaporation, condensation, boiling
- User logic determines the volume flow rate through these connectors so that the volumes of the lumps in each respective region remains constant within a small percentage
- Avoids lumps from becoming too small or too large relative to one another, and consequently avoids the problem of having very small lumps to somehow “disappear”
- Converted “balloon-like-behaving” lumps with IFACES to something more like a “fixed volume” approach (still at constant pressure)
SINDA/FLUINT Stratified Tank Setup

Fig 2: Stratified Tank Heat Transfer

Axial Wall Conductor

Wall Heat Flux (Can Be Nonuniform)

Fluid Heat Flux $\text{Nu} \sim 0.57 \text{ Ra}^{0.2}$
S/F QTIES (2 Sets):
- “Mixing Heat Transfer” $\text{Nu} \sim \text{Ra}^{0.33}$
  - Based on the $\Delta T$ Between Lumps
- Boundary Layer $\text{mdot} \times \text{Cp} \times \Delta T$
  - One Directional -> “UP”

Fig 3: Stratified Tank Heat and Mass Transfer
• **Thermal boundary layer** that forms along the tank wall, due to wall heat leak, is **modeled empirically** using correlations for free convection.

• Although the **two dimensional flow dynamics** of the boundary layer could not directly be incorporated into the one dimensional stratified tank model, it is **incorporated in a one dimensional sense**. Within each fluid lump the following boundary layer characteristics are determined:
  – Characteristic velocity
  – Boundary layer thickness
  – Buoyancy driven volume flow rate
SINDA/FLUINT Vapor Liquid Interface Modeling

- SINDA/FLUINT contains pre-built utility functions to model heat and mass transfer between a liquid and vapor interface (TWIN TANKS)
- For more modelling flexibility, user logic could incorporate the necessary physics to model a wide variety of scenarios:

LIQUID LEVEL -> VAPOR/LIQUID INTERFACE:
- Modelled as a PLENUM (Boundary State)
- TSAT = Saturation Temperature of “Top” Liquid Lump (Updated Every Iteration)

A S/F FTIE is placed between the “bottom” vapor lump (Tvap) and this boundary PLENUM
A S/F FTIE is placed between the “top” liquid lump and the boundary PLENUM

Fig 4: Vapor Liquid Interface Model
• The heat rates for these FTIEs are defined as follows:

\[
\begin{align*}
Q_{\text{FTIE}_{\text{Evap}}} &= h \times A_{\text{INTERFACE}} \times (T_{\text{VAP}} - T_{\text{INTERFACE}}) \\
Q_{\text{FTIE}_{\text{Eliq}}} &= h \times A_{\text{INTERFACE}} \times (T_{\text{INTERFACE}} - T_{\text{LIQ}})
\end{align*}
\]

• where,

\[
\begin{align*}
h &= \frac{\text{Nu}}{D_{\text{INTERFACE}}} \times k \\
\text{Nu} &= \text{const} \times \text{Ra}^{(1/3)} \\
\text{const} &\sim 0.04 \times \text{Function(Height/Diameter)}
\end{align*}
\]

• The \textbf{net evaporation rate at the interface} is calculated to be:

\[
\text{mdot}_{\text{EVAP}} = \frac{(Q_{\text{FTIE}_{\text{Evap}}}- Q_{\text{FTIE}_{\text{Eliq}}})}{(\text{heat of vaporization})}
\]
• **Evaporation** is modeled via the process:
  – Liquid leaves the “top” liquid lump and enters a DUMMY PLENUM
  – Vapor enters the “bottom” vapor lump from a DUMMY vapor PLENUM

• **Condensation** is modeled via the process:
  – Vapor leaves the “bottom” vapor lump and enters a DUMMY PLENUM
  – Liquid enters the “top” liquid lump from a DUMMY liquid PLENUM

• The DUMMY PLENUMS are set at the saturation temperature of the “top” liquid lump (updated every iteration)

  **NOTE!**

• The mass flow rate, whether condensing or evaporating, should be at saturated conditions. However the “bottom” vapor and “top” liquid lumps may not be saturated. Thus when mass is removed from either of these lumps the amount of energy leaving these lumps needs to be adjusted to account for this discrepancy.
• K-Site LH2 Self-pressurization (1g)
K-Site LH2 Self-Pressurization (1g)

1. Lightweight insulated aluminum ellipsoidal tank
   - Internal volume: 175 ft$^3$
   - Tests conducted in vacuum chamber.
   - Tank is supported by 12 fiberglass composite struts.
   - Test article is enclosed by a cryoshroud whose temperatures are maintained with electrical heaters.
   - Tank insulated with 2 blankets of MLI.

2. Test fluid is liquid hydrogen

3. Steady boil-off test and measurement performed at 95% fill and 117 kPa.

4. Tank fill level was reduced to desired fill level.

5. Several hours of additional venting at 103 kPa to achieve stationary state.

6. Self-pressurization tests were initiated from stationary stratified state.

• K-Site LH2 Axial Jet (1g)
• Same Tank as K-site LH2 1g Self-pressurization experiments. Pump and jet nozzle (mixer unit) was hardware designed for Shuttle Centaur LH2 tank and installed in K-site LH2 tank.

• Jet nozzle and location not changed during axial jet runs, but the jet flow rate was varied.

• Only considering test runs where self-pressurization was used to pressurize tank before turning on jet (Test Series A and B). Tank typically pressurized to 186 kPa before initiating jet.

• Experimental data is available for: tank heat load, ullage pressure, fluid temperature rake, wall temperatures, jet flow rates.
