Described herein are particular embodiments relating to a microfluidic device that may be utilized for cell sensing, counting, and/or sorting. Particular aspects relate to a microfabricated device that is capable of differentiating single cell types from dense cell populations. One particular embodiment relates a device and methods of using the same for sensing, counting, and/or sorting leukocytes from whole, undiluted blood samples.

MICROFLUIDIC DEVICE

CROSS-REFERENCE TO RELATED APPLICATIONS

This present application is a divisional of U.S. Ser. No. 12/062,808, filed Apr. 4, 2008, currently pending, which claims the benefit of priority of U.S. provisional application No. 60/922,296, filed Apr. 6, 2007, the contents of which are herein incorporated by reference in their entirety.

STATEMENT OF GOVERNMENT INTEREST

This work was supported in part by the National Space Biomedical Research Institute through NASA, grant number NCC 9-58-317. The United States government has certain rights in this invention.

FIELD OF THE INVENTION

The present disclosure relates to fabricated microfluidic devices that can be utilized as cell sensors and/or actuators. In certain embodiments, the microfluidic device may be used for labeling, sensing differentiating, and/or sorting targets, particularly cell populations.

BACKGROUND OF THE INVENTION

Standard cell sensors or actuators are generally based on flow cytometry and employ one or a combination of electrical impedance sensing, light scattering measurement, and chemical or immuno staining followed by optical sensing.

Alternative optical methods are based on light scattering and fluorescence staining of organelles, granules, and nuclei. Generally, low-angle scattered light contains information on cell size and high-angle scattered light can be used to probe internal composition of the cell. To achieve 5-part differential, certain leukocyte populations, such as eosinophils, require special stain to change its scattering characteristics from other granulocytes, and basophils typically need to be counted separately following the differential lysis of other leukocytes. McKenzie, Clinical Laboratory Hematology, Prentice Hall, 2004; Fujimoto, Sysmex J. Int. 9 (1999).

In general, conventional automated cell analyzers are bulky, expensive, and mechanically complex, which restricts their locations to hospitals or central laboratories. Conventional cell analyzers require larger sample volumes and generate more waste than the systems developed using microdevices. Furthermore, for analysis of certain cell types, such as leukocytes, accuracy and speed of counting, differentiation, and/or sorting is important for determining disease state and treatment.

SUMMARY OF THE INVENTION

Certain embodiments disclosed herein include a microfluidic apparatus comprising a substrate having a first channel having a defined physical feature, wherein said first channel is in fluid communication with at least one inlet for receiving a fluid, wherein said first channel leads to a restrictive access, and wherein said first channel is in fluid communication with a second channel having a defined physical feature, wherein said second channel is in fluid communication with at least one fluid flow outlet; and a fluid biological sample. In certain embodiments, said defined physical feature is a depression or a protrusion. In particular embodiments, said fluid biological sample comprises blood. In certain embodiments, the microfluidic apparatus further comprises a detection zone, and/or a filter array, each in fluid communication with said channel and said fluid flow outlet.

A microfluidic apparatus comprising a substrate having at least one first channel having a defined physical feature; at least one first inlet formed in said first channel for receiving a first fluid; wherein said first channel is in fluid communication with a bifurcated channel, wherein said bifurcated channel is in fluid communication with a second channel having a first detection zone; at least one second inlet for receiving a second fluid, wherein said second inlet is in fluid communication with a branched channel; a filter structure in fluid communication with a reservoir, wherein said reservoir is in fluid communication with said third channel detection zone; at least one fluid flow outlet formed in said third channel; and a fluid sample; wherein the ratio of the cross-sectional area of said second channel compared to the cross-sectional area of said first channel is 1:10. In certain embodiments, the defined physical feature is a depression or a protrusion.

In certain embodiments, said filter structure comprises a filter array, said first fluid comprises sheath fluid and said second fluid comprises blood.

Certain embodiments disclosed herein relate to a detection system comprising microfluidic apparatus and further comprising a light source; a lens assembly; a filter assembly; and an image capture device. In some embodiments, the detection system further comprises at least one display unit or at least one recording unit. In certain particular embodiments, said excitation source comprises a laser, particularly an argon laser. In particular embodiments, said filter assembly comprises an excitation filter, and at least one emission filter. In certain embodiments, said filter assembly further comprises a detection zone, and/or a filter array, each in fluid communication with said channel and said fluid flow outlet.

In certain embodiments, the detection system comprises an argon laser; said lens assembly comprises a condenser lens, an objective lens, and a beamsplitter; said filter assembly comprises an excitation filter, at least one emission filter; said image capture device comprises a photomultiplier tube, and said display unit comprises a personal computer.

In particular embodiments, said excitation source comprises a laser, particularly an argon laser; said lens assembly comprises a condenser lens, an objective lens, and a beamsplitter; said filter assembly comprises an excitation filter, at least one emission filter; said image capture device comprises a photomultiplier tube, and said display unit comprises a personal computer.

Other embodiments disclosed herein relate to a method for identifying a target comprising providing a fluid sample to at least one microfluidic apparatus, wherein said fluid sample contains at least one dye; providing an excitation source to induce at least one fluorescent signal in a target; detecting the fluorescent signal using as sensor in the apparatus; and identifying the target based on the analysis of the fluorescent signal. In certain embodiments, said target is selected from the group consisting of cells, organelles, nuclei, granules, DNA, and RNA. In other embodiments, said target comprises a cell selected from the group consisting of a monocyte, a granulocyte, a macrophage, a neutrophil, an eosinophil, a basophil, or other leukocyte. In specific embodiments, said target comprises a leukocyte and said dye comprises acridine orange. Particular embodiments of the method further comprising counting or sorting the target in the sample by analysis of the fluorescent signal. In certain embodiments, said fluid sample comprises blood.

DETAILED DESCRIPTION OF THE INVENTION

The present disclosure relates to fabricated microfluidic devices that can be utilized as cell sensors and/or actuators. In certain embodiments, the microfluidic device may be used for labeling, sensing, differentiating, and/or sorting cell populations.

In the area of optical sensing, microfabrication has allowed development of microdevices to replace glass capillary-based flow chambers, and to integrate compact optics and provide on-chip sample transport.

Cell sensing and counting, particularly of leukocytes, is cumbersome due in part to the cell population numbers. For leukocyte differential in microdevices based on optical sensing, a V-groove microchannel was fabricated by anisotropic wet etching of a silicon substrate and 3-part leukocyte differential was demonstrated for diluted blood without sheath flow by two-parameter light scattering. Altendorf, Proceedings of the Int'l Conference on Solid State Sensors and Actuators, v. 1, p. 531 (1997).
However, until the instant embodied disclosure, it was necessary to dilute cell samples for cell sensors and actuators for many reasons. One reason dilution has been necessary is in order to prevent the coincidence effect in which multiple cells appear in the detection zone simultaneously. In human blood, the ratio of erythrocytes, or red blood cells, to leukocytes is on the order of about a thousand to one, a dilution factor of from about one hundred to several tens of thousands is typically required to avoid erythrocyte interference for electrical impedance or light scattering detection. Furthermore, for counting leukocytes in samples where leukocytes are specifically fluorescently labeled, a dilution of at least ten times is usually required. Sheenan and Storey, *J. Pathol. Bacteriol.* 59; 336 (1947); Kass, *J. Clin. Pathol.* 76; 810-12 (1981); Weigl et al., *Biomed Microdev.* 3; 267-274 (2001).

Dilution is also often required in order to avoid clogging sample chambers, and also in order to remove erythrocytes that are lysed prior to running the sample, particularly for electrical impedance or light scattering detection. Some of these protocols also require an additional fixation buffer.

**Dyes**

In the present disclosure, a dye, such as Acridine orange (3,6-dimethylaminacridine, FIG. 1), can be used to differentiate a target, such as cells, organelles, granules, nuclei, molecules (including double or single stranded nucleic acids, such as DNA, or RNA, chromosomes, and also including synthetic forms). In one particular embodiment, leukocytes may be detected, counted, or sorted without need for lysing erythrocytes or fixing the cell sample. Certain dyes, such as Acridine orange, are also desirable due to the fast diffusion into cells, easy commercial availability, and excitation and emission wavelength compatibility with common light sources (i.e. argon laser and other broad spectrum light sources in visible range) and optical filters. Kosenow, *Acta Haematol.* 7, 217 (1952); Schiffer, *Blood* 19, 200 (1962); Jackson, *Blood* 17, 643 (1961); Hallermann et al., *Verh Deutsch Ges Inn Med.* 70, 217 (1964).

Acridine orange is a pH-sensitive fluorescent cationic dye that binds to double-stranded DNA by electrostatic attraction and intercalation of the Acridine orange between base pairs. Upon binding, the excitation maximum becomes 502 nm and the emission maximum becomes 525 nm (green). Acridine orange also binds to RNA and single-stranded DNA, with a shifted excitation maximum of 460 nm and an emission maximum of 580 nm (red). Adams and Kamentsky, *Acta Cytol.* 15, 289 (1971); Adams and Kamentsky *Acta Cytol.* 18, 389-91 (1974); Steinkam et al., *Acta Cytol.* 17, 113-17 (1973). Acridine orange is also desirable in that it is hydrophobic in neutral pH, and can easily diffuse through the cell membrane and cell nuclear membrane to bind to RNA and DNA. In living cells, Acridine orange is protonated in the acidic environment of lysosomes, which makes it cationic, and prevents the dye from leaking out of lysosome membranes. Moriyama et al., *J. Biochem.* 92; 1333-36 (1982). When Acridine orange is used for leukocyte analysis, the cell nucleus is stained green with slightly mixed red, a result of double-stranded DNA and single-stranded RNA while the cell cytoplasm is stained red due to the RNA and lysosomes. Thus, leukocyte counting can be achieved easily by using the strong signal from the green fluorescent channel. Leukocyte differentiation can be achieved by analyzing the signal from the red fluorescence channel.

For fresh-stained leukocytes, a 3-part differential (lymphocytes, monocytes, and granulocytes) can be achieved by studying the red fluorescent signal of an Acridine orange stained diluted blood sample, whereas a 5-part differential leukocytes (lymphocytes, monocytes, neutrophils, eosinophils, and basophils) has been demonstrated with hypotonic dilution and fresh Acridine orange-stained leukocyte samples. Adams and Kamentsky, *Acta Cytol.* 15, 289 (1971); Adams and Kamentsky, *Acta Cytol.* 18, 389-91 (1974); Steinkam et al., *Acta Cytol.* 17, 113-17 (1973). Other dyes can be utilized with certain embodiments described in the instant disclosure, such as ethidium bromide, three-dye combinations (ethidium bromide, brilliant sulfuraflavin, and stilbene disulfonic acid derivative); oxazine dyes, basic orange 21, and a polymethylene dye. Shapiro et al., *Histoch. Cytochem.* 24, 396-411 (1976); Shapiro et al., *J. Histoch. Cytochem.* 25, 836-844 (1977); U.S. Pat. No. 4,376,820; U.S. Pat. No. 4,882,284; Tibbe et al., *Nat. Biotechnol.* 17, 1210-1213 (1999); U.S. Pat. No. 4,400,570; Kass, *J. Histoch. Cytochem.* 36, 711-715 (1988).

**Apparatus**

One embodiment of the instant disclosure relates to a device or apparatus for cell counting and/or differentiating. In particular embodiments, the device or apparatus comprises a substrate formed from a material, such as silicon, glass, plastic, metal, or other material. One particular embodiment of the instant disclosure was fabricated using soft lithography. Quake, *Science* 290, 1536-40 (2000). Other photolithographic or etching techniques could also be used, according to specific embodiments.

One embodiment of the device was microfabricated using two parts of PDMS (polydimethylsiloxane) (Sylgard 184, Dow Corning, Mich., USA) mixed vigorously in 10:1 ratio. After degassing in vacuum for about 30 minutes, the mixture was poured onto DRIE-etched silicon mold, that had been pretreated with HMDS (hexamethyldisilazane) for easy separation after baking. The molds were baked at 80°C for 30 minutes. The hardened PDMS was separated from the silicon mold, and PDMS sheet was cut into pieces and fluidic access holes were punctured on each piece with a Luer stub adapter (Becton Dickinson, NJ, USA). Each PDMS piece was carefully placed on a cleaned glass slide and baked overnight at 80°C. In some cases, oxygen plasma treatment (300 m Torr, 25 W, 30 s) was used for PDMS and glass slides in order to improve adhesion between them, particularly with devices that were intended to be reused. Bhattacharyya et al., *J. Microelectromechan. Syst.* 14, 590-97 (2005).

In one particular embodiment, the channel structure was molded on a 1 cm x 1 cm PDMS block, with the thickness of the PDMS block at less than 3 mm. In one particular embodiment the channel depth was 16 μm in order to accommodate large leukocyte sizes.

One exemplary embodiment of the device is shown in FIG. 2. For this particular embodiment, a first fluid flow inlet 200 allows for deposition of, for example sheath flow fluid, and is in fluid communication with a bifurcated channel with a first channel arm 260 and a second channel arm 270 that both converge at a junction of a reservoir 290 and the detection zone 240. In this particular embodiment, the apparatus further comprises a second fluid flow inlet 210 that allows for deposition of, for example, a sample fluid, such as blood, that is in fluid communication with a filter array structure 230, by way of a branched sample flow zone 220 and a fluid flow outlet 250. In this particular exemplary embodiment, 2-D hydrodynamic focusing was adopted to control the particle position of the cell sample in the detection zone 240. According to the embodiment shown in FIG. 2, the ratio of cross-sectional area of sheath flow to core sample flow was 10:1, and the channel width of the detection zone 240 was 50 μm, with the width of the focused sample flow preferably 5 μm or less. In particular embodiments, the channels comprise a physical feature, such as a depression or a protrusion.
One exemplary embodiment of the device is shown in FIG. 13A. For this particular embodiment, the fluid flow inlet 1340 allows for deposition of a sample fluid, such as a biological sample, or other fluid sample containing a target. In one particular embodiment, the biological sample includes a cell sample, such as blood. In this exemplary embodiment, the fluid inlet is in fluid communication with the first channel 1330 which contains a restrictive access 1320 that is juxtaposed to a second channel 1310 which comprises the detection zone which is also in fluid communication with the fluid flow outlet 1300. In certain embodiments, the height of the first and/or second channels is approximately 5 µm, approximately 10 µm, approximately 15 µm, approximately 20 µm, approximately 25 µm, approximately 30 µm, approximately 40 µm, or any value therebetween. In certain embodiments, the width of the second channel is approximately 5 µm, 10 µm, approximately 15 µm, approximately 20 µm, approximately 25 µm, approximately 30 µm, approximately 35 µm, approximately 40 µm, or any value therebetween. In the exemplary embodiment shown in FIG. 13A, the second channel width was approximately 20 µm in size.

One exemplary embodiment of the device is shown in FIG. 13B. For this particular embodiment, the fluid flow inlet 1440 allows for deposition of a sample fluid, such as a biological sample, or other fluid sample containing a target. In one particular embodiment, the biological sample includes a cell sample, such as blood. In this exemplary embodiment, the fluid inlet is in fluid communication with a first channel 1430 which contains a restrictive access 1420 that is juxtaposed to a second channel 1410 which comprises the detection zone which is also in fluid communication with the fluid flow outlet 1400. In certain embodiments, the height of the first and/or second channels is approximately 5 µm, approximately 8 µm, approximately 10 µm, approximately 12 µm, approximately 15 µm, approximately 20 µm, approximately 25 µm, approximately 30 µm, approximately 40 µm, or any value therebetween. In certain embodiments, the width of the second channel is approximately 5 µm, 10 µm, approximately 15 µm, approximately 20 µm, approximately 25 µm, approximately 30 µm, approximately 35 µm, approximately 40 µm, or any value therebetween. In the exemplary embodiment shown in FIG. 13B, the second channel width was approximately 30 µm in size.

Certain embodiments of the device use a focused laser source for illumination, since cell focusing in the detection zone 240 is highly desirable. However, other embodiments included in the present disclosure use a more uniform diffused light source and a slit aperture. Such embodiments utilize straight channel geometry without cell focusing. In one embodiment, the channel length of the detection zone 240 is 1000 µm. A filter structure 230 upstream of the sample flow zone 220 may also be included in certain embodiments, which filtered out contaminants, including erythrocyte rouleaux, and other large particle aggregates to prevent clogging in the detection zone 240. In certain embodiments, the size of the rectangular pillar structure components of the filter structure 230 was 200 µm × 40 µm. The spacing between the pillars in each of the three rows was 40 µm, 30 µm, and 20 µm respectively, which allows for even the largest leukocytes to pass through the filter region 230.

System

The optical system was set up on an optical bench as shown in FIG. 3 (transmitted laser-induced fluorescent detection system or LIF). In one particular embodiment, the system setup comprises an excitation or laser source 300, a lens assembly 340, a microfluidic apparatus 350, an optional additional lens assembly 360, a filter assembly 320, 330, and an imaging capture device 390, 305. In certain embodiments, one or more emission filters comprise the filter assemblies 320, 330. In certain embodiments, the image capture device 395 comprises a charge-coupled device (CCD) camera, a complementary metal-oxide-semiconductor (CMOS) device, or a photomultiplier tube (PMT) device. In particular embodiments, the image capture device 395 may be coupled to communicate with a display unit or computing device 396, such as a personal computer. One of skill in the art would recognize that multiple and various computer software programs are available that allow for integration, compilation, analysis, reconfiguration, and other manipulation of data received from the system, particularly by way of the computing device 396. In one particular embodiment, the illumination system includes an argon laser (National Laser LC210BL, 488 nm, and 15-30 mW) available, Salt Lake City, Utah, USA) is used as the excitation source. An aperture 310 of 50 µm diameter is put in front of the laser output to facilitate, the alignment process and lower the illumination intensity. In certain embodiments, an optional laser-line bandpass filter (bandwidth equal to about 1.9 nm with a central wavelength of 488 nm) is used to further purify the laser source. In certain other embodiments, an optional neutral density filter (NDF) is used to attenuate laser excitation. Alternatively, the pinhole and NDF are replaced by two linear glass polarizers (Edmond Optics TECH SPEC, Barrington, N.J., USA) so that the illumination level on the device can be easily adjusted.

In one particular embodiment, a long-working-distance microscope objective (USMCO M Plan Apo, 10x, 0.28 NA, Dayton, Nev., USA) is used as a condenser lens 340. Another long-working-distance microscope objective (Bausch & Lomb, 50x, 0.45 NA, Rochester, N.Y., USA) is used as an objective lens 380. In the same embodiment, three emission filters 320 are used in one particular test: 488 nm long pass filter (Chroma H1500 LP, transition width<4.9 nm, edge steepness=2.5 nm, Rockingham, Vt., USA), a green bandpass filter with central wavelength 525 nm and a bandwidth 50 nm (Chrome D525_50 m), and a red bandpass filter with central wavelength 650 nm and bandwidth 50 nm (Chrome D650_50 m). A broadband non-polarizing hybrid cube beamsplitter 370 (Newport 05BC17MB.1, 400-700 nm, R/T=45%/45%, Irvine, Calif., USA) is used to direct light to the photodiode detector 380 and CCD camera simultaneously.

The signal is electrically amplified and detected either with a silicon photodiode receiver module 390 (Electro-Optical Systems, UVS-025-H, Phoenixville, Pa., USA) or a photon multiplier tube (PMT, Hamamatsu H5784-20, Japan). The voltage signal is sent to a deep memory oscilloscope (HP 54645A, Palo Alto, Calif., USA). When the buffer in the oscilloscope is full, the data can be loaded to a computer and analyzed with a Matlab peak-detection program. Video may be taken with an analog CCD camera (Hitachi KP-D20B, Japan) at 30 frames per second and then converted to digital format and stored in a computer 396. Other imaging capture devices 395, such as CMOS, PMT, or still other devices may also be used with particular embodiments described herein. In certain exemplary test runs, the system set up utilizing a photodiode detector and PMT are more sensitive than the CCD camera and have a faster time response. During one exemplary test run, the optical system was first roughly aligned on a dummy device with the aid of images from CCD camera. A 10 µm diameter illumination spot on the detection zone is easily achieved with proper alignment.
As can be seen in FIG. 5, the exemplary embodiment utilized in cell detection did not experience any significant photobleaching. The signal was fitted as a first-order exponential decay with time constant of 6.4±0.7 seconds. Two more tests confirmed that the photobleaching time constant for one particular embodiment was between 1 second and 10 seconds. The photobleaching time constant for one particular embodiment was characterized by filling the device with Acridine orange-stained whole blood. The channel was scanned by the laser spot and the illumination was set to be the same as that used in testing. The entire process was recorded with a CCD camera. Whenever a fluorescing leukocyte was observed with fluorescent emission clearly distinct from the background, we stopped moving the laser spot and waited until the leukocyte was photobleached to background level. The images were extracted from the video, converted to 8-bit gray scale images, and analyzed with a Matlab program. The data was fitted to a single time-constant exponential decay.

Additionally, green fluorescent beads were tested at a concentration of about 2×10^9/mL, as observed by CCD camera, and shown in FIG. 6. Sample flow rate was set at about 3 nL/min, and sheath flow was about 30 nL/min. In one exemplary test run, a hydrodynamic focused laser beam, as shown in FIG. 6A, created an enlarged light circle as shown in FIG. 6B. Only a single bead normally appeared in each image. With diffused laser illumination, as shown in FIG. 6C, the trace of the bead could be identified, as shown in FIG. 6D. Hydrodynamic focusing limits the cross-sectional area of the detection zone without shrinking the channel diameter, thus the signal-to-noise ratio may be improved without increasing the risk of clogging the channel. Also, the reduction of the cross-section of the core flow reduces the coincidence effect. Finally, enclosing the core sample flow with sheath flow minimizes fluorescent dye absorption in the device walls, thus reducing background noise. As indicated in FIG. 7, bead signals from the photodiode detector could easily be identified.

As shown in FIG. 8, using both red and green emission filters, images extracted from video taken by the CCD camera show the signal identified from a leukocyte stained with Acridine orange, as well as the signal obtained from the fluorescent control bead. For photodiode detection, the expected leukocyte detection rate would average about 4-11 cells per second for a normal individual.

In one exemplary embodiment, a time trace over 50 seconds of an undiluted blood sample stained with Acridine orange using a green emission filter, and a throughput of up to about 1000 leukocytes per second was attained. Maxima signal intensity (peak height as in FIG. 9) from the green fluorescent channel with 525 nm emission filter was measured by plotting its histogram, as shown in FIG. 10. As expected, the lower-intensity portion is likely dominated mainly by lymphocytes, while the higher-intensity portion is likely mainly from monocytes, with the center-region is likely mostly from granulocytes, Steinke et al., Acta Cytol, 17; 113-117 (1973).

In one exemplary embodiment, a time trace over 50 seconds of an undiluted blood sample stained with Acridine orange using a red fluorescent channel with 650 nm emission filter was conducted. As shown in FIG. 11, two peaks were identified, the lower intensity is dominated by lymphocytes and the higher-intensity peak is largely monocytes and granulocytes. The time between the start of staining the cells to photodiode recording was typically greater than 15 minutes.

In both exemplary studies, the maximal throughput was about 1000 leukocytes per second utilizing one embodiment of the PMT detector. By using undiluted blood, minimal
11. The method of claim 1, wherein the method further comprises recording the level of fluorescence of the fluorescently labelled leukocytes and a level of fluorescence of the fluorescently labelled control beads, as they pass through the detection zone in the second microfluidic channel, whereby decreasing the cross-sectional area increases a core flow rate of the modified blood sample, such that the core flow rate is from approximately 5 microliters/minute to approximately 150 microliters/minute, or any value therebetween, to approximately 1000 microliters/minute.

12. The method of claim 1, wherein the excitation source comprises a light-emitting diode (LED).
17. The method of claim 1, wherein the measurement of the fluorescence comprises using an image capture device.

18. The method of claim 1, wherein the flow of the modified blood sample is performed by pumping the fluid sample through the microfluidic device.

19. The method of claim 1, wherein the modified blood does not comprise a sheath fluid.
