Autonomous Control (AC) refers to control actions of a system that take place without intervention from humans.

AC denotes control actions that respond to events that are unexpected, and enable the system to continue on a path to achieve an original objective or alternate objectives.

Autonomous Control incorporates concepts such as adaptation, mitigation, and re-planning in space and time.
Autonomy is a capability that is not absolute. There are degrees of autonomy, ranging from low levels to high levels, but there is no maximum level (how many autonomy strategies are implemented?).

It is an evolutionary capability that can handle increasing degrees of complexity for reasoning and decision making.

It must know the condition of the system elements and their ability to carry out the task. Integrated System Health Management (ISHM) then becomes an enabler for autonomy.
• Strategies for autonomy guide the decision making process. What to do when an element cannot be used? There must be a strategy to replace the function of that element in the current plan.

• Autonomy is scripted to apply strategies, but it is more powerful when scripted at a high level of abstraction, that is, at a more generic KNOWLEDGE level. Where concepts are used instead of just data and information.
During a mission, autonomy is achieved with four knowledge domains: System Domain Model (SDM), ISHM Domain Model (IDM), Autonomy Domain Model (ADM), and Mission Planning Domain Model (MPDM).

ISHM determines health and updates the SDM, Planner determines a course of action, and autonomy strategies help the Planner modify the course of action while considering health and objectives of a mission.

Mission Planning

Plan Sequence

Sensor and Component Health

Autonomy Strategies
The software must enable the creation of domain models of the system which encapsulates information and knowledge about all elements of the system and processes that can take place throughout the system (a knowledge base).

The software and hardware architectures must make possible data, information and knowledge (DIAK) management, such that data and information is available to any element of the system when needed and for the right context.
Example Domain Model Representation
Hardware architecture showing for distributed ISHM-AC capability implementation.
AC-ISHM Integration Architecture
Software Architectures

- Software architectures for ISHM and Autonomy must enable the implementation of paradigms to employ knowledge and information to achieve the desired functional capabilities.
- In the case of ISHM, the goal is to determine the condition of every element in the system, by addressing the following: (1) anomaly detection, (2) diagnostics, (3) prognostics, (4) user interfaces for integrated awareness by the operator.
- A software architecture for autonomy should enable the following capabilities:
  - Mission planning.
  - Resource assessment for mission execution.
  - Strategies to address availability of resources to carry out a mission.
  - Strategies for mission re-planning to deal with unexpected circumstances.
Domain Models and Basic Knowledge Constructs

- Domain models are needed to encapsulate information and knowledge associated with the system that is to operate autonomously.
- Four domain models provide the foundation for autonomy: (1) System Domain Model (SMD), (2) ISHM Domain Model (IDM), (3) Autonomy Domain Model (ADM) and (4) Mission Planning Domain Model (MPDM).

Update SDM

Mission

Autonomous Plan Sequence
• **System Domain Model (SDM)**
  – This is the application domain model.
  – Encapsulates all elements in the system, generally created from design diagrams (e.g. piping and Instrumentation diagrams or P&IDs).

• **ISHM Domain Model (IDM)**
  – Encapsulates knowledge to achieve ISHM functionality (anomaly detection, diagnostics, prognostics, user interfaces for integrated awareness.
  – Uses the SDM and updates ISHM parameters in the IDM to be consistent with the current condition of its elements.
**Autonomy Domain Model (ADM)**
- Strategies to enable autonomy.
  - Determination of potential replacement elements (e.g. sensors).
  - Determination of alternate flow paths.
- Uses DlaK from the SDM and system condition information from the IDM.

**Mission Planning Domain Model (MPDM)**
- Creation of mission plans to achieve an objective.
- Real time modification of mission plans guided by information from the ADM.
- Uses DlaK from the SDM.
• DlaK to implement autonomy has a substantial portion of re-usable code.
• Strategies for health management and autonomy can be applied to many classes of systems.
• The reason is that these strategies are founded in engineering principles that apply to classes of systems.
• For example a leak detection strategy may be to observe isolated subsystems (subsystems isolated by valves that are closed), and see if pressures are not steady.
Autonomous systems are intelligent systems by definition.

They incorporate information and knowledge that is evolving in time.

Architectures and software environments for autonomy must enable systematic evolution of the capability.

For example, any time there is a new strategy to determine that a sensor is faulty, one should be able to implement that strategy and make it part of the existing knowledge base of the domain model in a systematic manner, without affecting existing code. And the new strategy should be integrated automatically.

Liquid State

Gaseous State
1. Sequence Creation, loading, and execution.
   a. Sequences can be seen as mission plans.
   b. The system enables quick and easy creation of sequences with menus.
   c. Sequences are represented in tabular and graphical formats.
   d. Sequences can be verified by simulating conditions that enable actions to be executed.
   e. Sequences can be saved and loaded as needed.
   f. Sequence conditions include:
      a. Sensor triggers.
      b. Redline triggers.
      c. Fluid saturation state.
      d. Redline sensor failure
      e. May include other conditions from health or other algorithm outcomes.
   g. Sequence actions include:
      a. Valve and pump operations.
      b. Camera pointing.
      c. Execution of special sequences such as shut-down or reverting to a prior step.
      d. May include execution of any sequence that responds to system conditions and planning.
