NIAC Study Objective (2011 – 2014)

To develop an innovative yet practically implementable mitigation technique for the most probable impact threat of an asteroid or comet with short warning time (i.e., when we don’t have sufficient warning times for a deflection mission)
NIAC Phase 1 Proposal (2011)

• Late intercept missions, with short warning time < 1 yr, will result in a hypervelocity arrival closing (relative) velocity of 5 to 30 km/s.
• $\Delta V = 10$ km/s requires a 96% propellant mass (300-s Isp)
• $\Delta V = 30$ km/s requires a 99.99% propellant mass ratio
• Impact velocity of nuclear explosive devices (NEDs) is limited as 300 m/s max (2005 NRC Report on NEPWs)
Precision Terminal Intercept Guidance

Terminal Guidance Begins
Impact - 2 hrs
for 50- to 150-m target

Launch Vehicles
- Delta IV Heavy
  1500 kg NED
  (≈ 2 Mt yield)
- Delta IV M+
  1000 kg NED
  (≈ 1 Mt yield)
- Delta II Class
  300 kg NED
  (≈ 300 kt yield)

Civil Defense

Nuclear

Ready to Launch
Build and Launch
NIAC Project Outcomes (1/2)

- The Hypervelocity Asteroid Intercept Vehicle (HAIV) mission concept of blending a kinetic impactor with nuclear subsurface explosion

- 7 journal articles + 30 plus technical papers

- 3 Ph.D. (graduated) + 3 MS (graduated) + 3 Ph.D. (current)

- The HAIV mission concept should further exploit the ATLAS last alert system for active last-minute planetary defense (1 week – 3 weeks)
ATLAS Last Alert System
(Asteroid Terrestrial-Impact Last Alert System)

- A $5M project started in 2013 (due to the Chelyabinsk event)
- The ATLAS is currently scanning the sky with a prototype camera and telescope, and will be fully operational in 2015-2016.
- So far, only for civil defense (evacuation)
- One-day alert for a 8-m, 30-kt “town killer”
- One-week alert for a 45-m, 5-Mt “city killer”
- Three-week alert for a 140-m “county killer”

An early ATLAS design concept.
• If a HAIV/IPBM system (≈ $200M- $500M) becomes ready to launch at anytime in the future,
  
✓ **Given one-week warning from the ATLAS**, an asteroid (> 45 m) can be intercepted/fragmented far outside the orbit of moon.

✓ **Given three-week warning from the ATLAS**, an asteroid (> 140 m) can be intercepted/fragmented far outside Earth’s gravitational field.

• Note that ALL other “non-nuclear deflection” options will require much earlier warning of at least 10 to 20 years.

Approach Phase
The approach phase extends from 60 days before to five days before encounter. Sixty days out roughly coincides with the earliest time that the team expects the spacecraft to be able to detect comet Tempel 1 in its high-resolution camera. This milestone marks the beginning of an intensive period of observations to refine knowledge of the comet's orbit. Regular scientific observations will be used to study the comet's rotation, activity and dust environment.

Comet Encounter
The encounter phase begins five days before and ends one day after the impact with comet Tempel 1. This brief but very intense period includes two final targeting maneuvers, leading up to release of the impactor and its dramatic collision with the comet's nucleus. After releasing the impactor, the flyby spacecraft will execute a deflection maneuver so that it does not also collide with the comet; the maneuver will also slow it down enough to make observations after the impact and before flying past the nucleus.
