A cutting head for attachment to the end of the wire probe of an ultrasonic kidney stone disintegration instrument. The cutting head has a plurality of circumferentially arranged teeth formed at one end thereof to provide a cup-shaped receptacle for kidney stones encountered during the disintegration procedure. An integral reduced diameter collar diminishes stress points in the wire and reduces breakage thereof.

7 Claims, 1 Drawing Sheet
CUTTING HEAD FOR ULTRASONIC LITHOTRIPSY

ORIGIN OF THE INVENTION
The invention described herein was made by an employee of the U.S. Government and another and may be manufactured and used by or for governmental purposes without the payment thereon or therefor.

TECHNICAL FIELD
This invention relates to surgical apparatus for disintegrating urinary calculi, and, more particularly, to a cutting head and to an ultrasonic device for fragmenting or drilling through urinary calculi in situ.

BACKGROUND ART
The incidence of hospitalization for the removal of urinary calculi, commonly referred to as kidney stones, has been estimated to be as high as 200,000 cases per year. Stones which are quite small may in some cases be passed without hospitalization. However, in the remainder, the kidney stones become impacted in the ureter, a muscle tube joining the kidney to the bladder. An impacted kidney stone is a source of intense pain and bleeding, a source of infection, and, if the stone completely blocks the flow of urine for any extended length of time, can cause the loss of a kidney. Small stones which are lodged in the lower third of the ureter can be removed non-surgically by using a technique employing the well known Dormia stone basket. However, basket removal of a kidney stone usually fails if the stone is lodged in the upper ureter, is impacted, or is larger than one centimeter in diameter. In these cases, the only procedure by which the stone could heretofore be removed was through a serious surgical operation called a ureterolithotomy.

More recently, however, a non-surgical method for removing kidney stones has been developed. In this technique, the kidney stones are subject to a vibratory action, such as that provided by an ultrasonically vibrated wire probe. In one such apparatus, a catheter is placed cystoscopically at the site of the stone in the urinary tract, after which a long wire probe is passed through a lumen of the catheter and is brought into contact with the stone. The wire probe is attached to the ultrasonic transducer which, when energized, sets the wire probe into lateral and longitudinal vibrations. The vibrational energy is transmitted by the wire probe to the stone, causing it to fracture into small fragments which the patient can then pass spontaneously after withdrawal of the catheter.

While such apparatus can perform its intended function, a severe limitation has been found to exist due to slippage of the thin wire probe off the kidney stone and its lodgement between the stone and urinary tract. Attempts to ameliorate this situation by providing a wider tip cutting surface has resulted in premature breakage of the wire probe at the tip exiting the catheter near the kidney stone. This occurs because the vibrational energy, typically 20 KHz in frequency, in conjunction with the added cantilevered mass of the larger cutting area, causes the wire probe to snap off due to metal fatigue after 10-20 seconds of operation. This has been found to be insufficient time to complete the disintegration procedure, as well as dangerous because it leaves metal fragments in the urinary tract. A clear need, therefore, exists to prolong the operational life of the wire probe for a length of time adequate for completion of the procedure. A desirable time frame is typically one minute, which is substantially greater than that provided by known prior art apparatus.

STATEMENT OF THE INVENTION
Accordingly, it is an object of the invention to provide a cutting head for surgical use.

Another object of the present invention is to provide a cutting head member for an ultrasonically vibrated wire probe.

A further object of the instant invention is to provide a safer and more efficient cutting head for ultrasonically disintegrating kidney stones.

Still another object of the invention is to provide an improved system for prolonging the operational life of an instrument for disintegrating kidney stones.

Another further object of the present invention is to provide a device for seating of kidney stones within a cutting head in an ultrasonic lithotripsy procedure.

Yet another object of the present invention is to greatly enhance the fragmentation of kidney stones when using ultrasonic lithotripsy.

These and other objects of the present invention are provided by a cutting head which is attachable to the end of the ultrasonically vibrated wire probe. The cutting head includes a large diameter cutting section provided with a plurality of teeth formed on the periphery of one end thereof to present a cup-shaped receptacle to seat a kidney stone thereon. The member also includes a collar integrally formed with the cutting tip section to reduce stress points along the probe.

BRIEF DESCRIPTION OF THE DRAWINGS
The foregoing, as well as other objects, features, and advantages of the invention will become apparent from the following detailed description when taken in conjunction with the appended drawings in which like numbers represent the same or similar components throughout the several drawings, and wherein:

FIG. 1 is a side elevational view of state-of-the-art apparatus for fragmenting kidney stones; FIG. 2 is a side elevational view of the cutting head of this invention; and FIG. 3 is a longitudinal view, partly in section, of the cutting head in contact with a kidney stone.

DESCRIPTION OF THE PREFERRED EMBODIMENT
Referring to the drawings, and, more particularly, to FIG. 1, there is illustrated an ultrasonic kidney stone disintegration instrument in accordance with the prior art. The purpose of this Figure is to provide a better understanding of the invention to be described in detail in conjunction with FIGS. 2 and 3.

FIG. 1 shows a cystoscope 10 inserted through a patient's urethra 12 into a bladder 14. A catheter 16 is inserted through the cystoscope 10, the bladder 14, and into a ureter 18 until its far end 20 comes into proximity to a piece of urinary calculus, hereinafter referred to as a kidney stone, 22. A wire probe 24 is inserted through the catheter 16 until its far end 26 contacts the stone 22. The diameter of the wire probe 24 is substantially smaller than the lumen diameter of the catheter 16 so that any movement of the wire probe is not restricted by the catheter material. The opposite, or near end, 28 of the wire probe 24 is connected to the tip 30 of a mov-
able ultrasonic transducer assembly 32 which is mounted on a base 34. The base 34 includes a handle 36 having a trigger 37 which is connected to the transducer 32 for adjusting the position of the wire probe 24 against the stone 22 by a linear translation of the transducer assembly 32 on the base 34. Base 34 additionally includes an outward angular support member 38 which includes a connector element in the form of a catheter joint 40 for engaging and holding the near end of the catheter 16. The terminal portion of the wire probe is clamped to tip 30 of the transducer 32 by a set screw 42.

With the catheter 16 and wire probe 24 inserted into the ureter 18, end 26 of the probe is optically guided to make contact against kidney stone 22. Thereafter, the transducer assembly 32 is energized to provide lateral motion to the wire probe 24 and the probe is gently pushed against the stone.

The apparatus does not operate as desired when tip 26 of the wire probe slips off the surface of the stone 22, and slides past it as illustrated in the dotted line position of tip 26'. In this circumstance tip 26' does not perform its intended function. Increasing the surface area of the cutting tip causes it to break off from the probe 24 at end 20 of catheter 16, at the point of greater stress where it emerges from the catheter.

With the foregoing in mind, a cutting tip 44 shown in FIGS. 2 and 3 is attached to end 26 of the wire probe to overcome the problem of wire slippage and to greatly increase the cutting surface area. Tip member 44 provides two structural features, one of which prevents premature breakage of the wire probe at the point of its exiting the catheter 16, while the other assures seating of the kidney stone within the tip member 44.

Member 44 is of stainless steel construction and comprises two integrally formed coaxial cylindrical sections, an elongate collar section 46 which relieves stress, and a cutting tip section 48.

Member 44 is also provided with a central circular opening (not shown) which extends completely through collar section 46 and through most of cutting tip section 48. The opening has a diameter sufficiently wide so that it is just capable of being slid over wire tip 26. By inserting wire tip 26 through the opening as far as possible into the cutting tip section 48, the end of the cutting tip section is arranged to initially abut the kidney stone within the tip member 44. Tip member 44 provides an outward angular support member 38 which partially stays within the catheter 16 while the probe is gently pushed against the stone.

Member 44 is of stainless steel construction and comprises two integrally formed coaxial cylindrical sections, an elongate collar section 46 which relieves stress, and a cutting tip section 48.

With the foregoing in mind, a cutting tip 44 shown in FIGS. 2 and 3 is attached to end 26 of the wire probe to overcome the problem of wire slippage and to greatly increase the cutting surface area. Tip member 44 provides two structural features, one of which prevents premature breakage of the wire probe at the point of its exiting the catheter 16, while the other assures seating of the kidney stone within the tip member 44.

Member 44 is of stainless steel construction and comprises two integrally formed coaxial cylindrical sections, an elongate collar section 46 which relieves stress, and a cutting tip section 48.

With the foregoing in mind, a cutting tip 44 shown in FIGS. 2 and 3 is attached to end 26 of the wire probe to overcome the problem of wire slippage and to greatly increase the cutting surface area. Tip member 44 provides two structural features, one of which prevents premature breakage of the wire probe at the point of its exiting the catheter 16, while the other assures seating of the kidney stone within the tip member 44.

Member 44 is of stainless steel construction and comprises two integrally formed coaxial cylindrical sections, an elongate collar section 46 which relieves stress, and a cutting tip section 48.

With the foregoing in mind, a cutting tip 44 shown in FIGS. 2 and 3 is attached to end 26 of the wire probe to overcome the problem of wire slippage and to greatly increase the cutting surface area. Tip member 44 provides two structural features, one of which prevents premature breakage of the wire probe at the point of its exiting the catheter 16, while the other assures seating of the kidney stone within the tip member 44.

Member 44 is of stainless steel construction and comprises two integrally formed coaxial cylindrical sections, an elongate collar section 46 which relieves stress, and a cutting tip section 48.

With the foregoing in mind, a cutting tip 44 shown in FIGS. 2 and 3 is attached to end 26 of the wire probe to overcome the problem of wire slippage and to greatly increase the cutting surface area. Tip member 44 provides two structural features, one of which prevents premature breakage of the wire probe at the point of its exiting the catheter 16, while the other assures seating of the kidney stone within the tip member 44.

Member 44 is of stainless steel construction and comprises two integrally formed coaxial cylindrical sections, an elongate collar section 46 which relieves stress, and a cutting tip section 48.

With the foregoing in mind, a cutting tip 44 shown in FIGS. 2 and 3 is attached to end 26 of the wire probe to overcome the problem of wire slippage and to greatly increase the cutting surface area. Tip member 44 provides two structural features, one of which prevents premature breakage of the wire probe at the point of its exiting the catheter 16, while the other assures seating of the kidney stone within the tip member 44.

Member 44 is of stainless steel construction and comprises two integrally formed coaxial cylindrical sections, an elongate collar section 46 which relieves stress, and a cutting tip section 48.

With the foregoing in mind, a cutting tip 44 shown in FIGS. 2 and 3 is attached to end 26 of the wire probe to overcome the problem of wire slippage and to greatly increase the cutting surface area. Tip member 44 provides two structural features, one of which prevents premature breakage of the wire probe at the point of its exiting the catheter 16, while the other assured seating of the kidney stone within the tip member 44.

Member 44 is of stainless steel construction and comprises two integrally formed coaxial cylindrical sections, an elongate collar section 46 which relieves stress, and a cutting tip section 48.

With the foregoing in mind, a cutting tip 44 shown in FIGS. 2 and 3 is attached to end 26 of the wire probe to overcome the problem of wire slippage and to greatly increase the cutting surface area. Tip member 44 provides two structural features, one of which prevents premature breakage of the wire probe at the point of its exiting the catheter 16, while the other assures seating of the kidney stone within the tip member 44.

We claim:
1. A surgical cutting head for attachment to an ultrasonically vibrated wire probe, comprising:
   a cylindrical cutting tip section having a plurality of cutting teeth arranged circumferentially at one end thereof, said teeth being equidistantly spaced on said one end of said cutting tip section and having flat top ends and expanding three-sided cross sections along the length of said teeth to form a cup-shaped seat having inwardly projecting intersections formed by two sides of said three-sided cross sections to form cutting edges within said cup-shaped seat; and
   a cylindrical collar coaxial and integrally formed with the other end of said cutting tip section.
2. The cutting head of claim 1 wherein said collar and cutting tip sections are provided with a central bore along their common axis, said bore extending through said collar and partially through said cutting tip section.
whereby said head may be slid over the wire probe and swaged thereto.

3. The cutting head of claim 2 wherein the external diameter of said cutting tip section is larger than the external diameter of said collar section.

4. Surgical apparatus for disintegrating and dislodging urinary calculi lodged in the urinary tract, comprising:
   a catheter adapted to be inserted into the ureter to come into proximity of the calculi to be dislodged;
   a wire probe fed through said catheter;
   ultrasonic transducer means coupled to said wire probe for imparting vibrations thereto; and
   a cylindrical member including a cutting tip section joined to the end of said wire probe for contacting said calculi, said cutting tip section comprising a plurality of cutting teeth equidistantly spaced about the circumference of one end of said member, said teeth having flat top ends and expanding three-sided cross sections along the length of said teeth to form a cup-shaped seat to abut said calculi, said seat having inwardly projecting intersections formed by two sides of said three-sided cross sections to form cutting edges within said cup-shaped seat.

5. The apparatus of claim 4 wherein said cylindrical member further includes an elongate collar section coupled to and coaxial with said cutting tip section and wherein said member is swaged onto said wire probe.

6. The apparatus of claim 5 wherein the diameter of said wire probe is substantially less than that of said catheter and the external diameter of said collar section is at least twice as great as that of said wire probe, but less than the diameter of said catheter.

7. The apparatus as recited in claim 6 wherein said collar section partially stays within said catheter when said ultrasonic transducer is imparting vibrations to said wire probe.
