Our thinking

• Need to understand effects of aerosols on clouds and precipitation and eventually on Earth’s Radiation Budget

• Problem poses obvious observational challenges

• How to separate aerosol from all other effects?

• Breaking down the analysis by “regime” (group together similar conditions) may help

• But how do we define regimes?
  – Exploiting cloud appearance (from passive obs) is a starting point
  – This poses some constraint on environmental conditions
  – Additional constraints can be imposed

• So we proceed with a “cloud regime” (CR) analysis
  – Our CRs are based on MODIS
  – You may also know ISCCP “Weather States”
Where the CRs occur

CRs and large-scale vertical motion
Dataset and methodology

- 12 years of Aqua-Terra L-3 daily (D3) 1° data
  - Collection 6
- Joint histograms of CTP-TAU
- MODIS CRs from $k$-means clustering of CTP-TAU joints
- Aerosol Optical Depth (AOD)
  - We calculate seasonal AOD distributions and perform compositing at the vigintile level (20-bin distribution) of cloud properties and precipitation for each CR separately (Terra CR=Aqua CR)
  - We often focus on the upper (3Q, “high” aerosol) and lower (1Q, “low” aerosol) quartile and perform statistical significance test
  - Two ways to build AOD seasonal distributions: (1) for each gridcell (stronger constraint); (2) for each CR (weaker constraint)
- Precipitation data: GPCP-1DD
- Land/ocean separation illuminating
Sampling issues
(how to build AOD distributions)
AOD Determination

1) \[ \text{AOD} = \frac{(\text{Aqua AOD} + \text{Terra AOD})}{2}. \]

2) \[ \text{AOD} = \text{Aqua AOD} \quad \text{OR} \quad \text{AOD} = \text{Terra AOD} \]

3) \[ \text{AOD} = \frac{(\text{Aqua AOD}_1 + \text{Aqua AOD}_2 + \text{Terra AOD}_1)}{3}. \]

Summary and parting thoughts

• We propose that Aerosol-Cloud-Precipitation relationships be examined on a “cloud regime” basis
  o This helps us examine aerosol influence under more “similar” conditions

• Even then, the outcomes depend on how one samples AOD distributions (weaker or stronger constraints on meteorology)

• Most times, cloud property and precipitation differences between low and high aerosol loadings are small (albeit statistically significant)
  o But not always consistent with expectations (optical thickness, low cloud precip)
  o Enhancement of precipitation for most CRs for large AOD

• Important: our analysis cannot distinguish how AOD retrievals biases vary due to cloud presence within or across CRs

• Also working with TMPA precip (forthcoming) hoping to resolve more details (e.g. morning/afternoon contrasts)

The chart represents the cloud fraction percentages for different cloud types and regions. The chart shows the liquid cloud fraction (dark blue), ice cloud fraction (light blue), and total cloud fraction (pink) for regions CR1 to CR12.

MODIS Cloud Regime RFO (%)
Scatter plot comparing latitudinally-weighted mean precipitation rate (including zero precipitation) for upper 3q AOD and lower 1q AOD. The horizontal and vertical error bars indicate one fifth of the interquartile range of the distributions used to calculate the composite means; distance from median to 25% percentile is represented by the error bars below and to the left of the symbol while that to the 75% percentile by the error bar above and to the right. All the values are statistically significant with 95% confidence except CR2 (LAND).
