Method 1

Issues

Method 2

Issues

Next Steps
Method 1: ASRS Analysis

- Descend Via RNAV STARs
- \(\approx 400\) ASRS reports reviewed
- Deviation trends were categorized

Chains of events were coded by Initial and causal factor:

1st Initial
2
3
Last causal
Issues from ASRS Analysis

More than 80% of Deviations in 4 Categories

1. ATC Interventions
2. Automation
3. Procedure Design
4. Charting
ASRS Issue #1
ATC Interventions

• Runway and Approach changes during the STAR triggered issues.

  “Several approach clearance changes......
  expect Runway 35R RNAV RNPZ but mistakenly entered Runway 34R.
  After a TA alert.....”

• Altering charted restrictions
  – Changes physics of procedure

  “ATC specialists must not have any idea of the level of disruption the
  constantly changing speeds impose on the flight crew during arrival. In
  my opinion they truly need increased awareness of the destabilizing
  affect these speed changes have on a safe flight.”
ASRS Issue #2
Automation

- **FMS Entry errors**
  
  "late runway change as they approached HONIE on the WARRR RNAV STAR to ATL, the flight crew was unable to program it in a timely fashion and a modest track deviation Occurred"

- **Auto Flight Expectations**
  
  "We noticed we might be high by KIKKR and put full speed brakes out and kicked off the autopilot, the VNAV Path showed us on the descent path but we were high by up to about 1,000 foot"

- **Mismatched Capability**
  
  "We went 500 FT below the charted altitude crossing ARGAL... The altitude deviation occurred because the Captain put in a rate of descent that would allow us to cross the last fix [as required] versus the intermediate fixes."
Where is the most constrained segment?

ASRS Issue #3
Procedure Design

VANCO is gone

Whiny 1 RNAV arrival into DFW.
Star was loaded and confirmed by both pilots with emphasis on speed and altitudes especially being new stars.

With autopilot engaged in LNAV and VNAV Path, aircraft remained on path and speeded up even with full speed brakes deployed.

VANCO intersection to BERMS. ATC was notified and asked for relief. No scratchpad messages and light winds less than 10 knots.

ATC coordinator contacted on arrival.

Redesign intersection to provide more distance to allow greater flexibility.

Crossing 2000 feet in 4.4 at 250 knots is very tight in normal conditions.

Fixes?

VANCO is gone
ASRS Issue #4: Charting

Missed Notes
Method 2: 2015 Workshop

- Held at NASA Ames Moffett Field, CA
- To learn about design and issues
- To provide a forum and start dialog
- Attended by
  - FAA Safety, Airline Reps, NASA personnel.
- Presentations:
  - Non-VNAV airline operational concerns
  - Weather effects
  - Design problems in Boston
  - Complexity
Standardization In Design

• No requirement to include stakeholders in design process
  – Might miss valuable feedback or knowledge
  – Might not have the authority to make needed changes (e.g., airspace)

• No method to catalog fixes
  – Actionable fixes not available to others

• Aero modeling is not comprehensive
  – Flyability limits are unknown
Deviations from 4 major categories
1. ATC Intervention
2. Automation
3. Procedure Design
4. Charting
   - Are there other Categories? We need a larger pool of data. FOQA + ASAP = better picture
Summary & Next Steps

Design methods are not standardized leading to inconsistent results.

- Create a repository and forum for design problems, lessons learned, and best practices.

Increases in STAR implementation & functionality might be related to deviation occurrence rates.

- Need to know how often deviations occur- ATC data could possibly inform more accurately.
Unchecked Complexity Poses Future Risks
Thank You
