EO-1 Complementing Landsat 8 and MODIS

EO-1 ALI complementing OLI. When the Villarrica Volcano erupted, EO-1 was able to acquire an image on March 5, 2015 – **five days before** the next Landsat 8 overpass.

Landsat 8 OLI
Before Eruption

MODIS, August 31, 2014

ALI natural-color composite August 27 overlaid with an infrared (IR) night view from September 1, 2014

EO-1 ALI night-time image of the Vatnajokull volcano complementing MODIS (top).
EO-1 image of Wolf Volcano in Galapagos
Eruption on May 25th, image acquired on May 28th

EO-1 ALI night-time image of Holuhraun Iceland volcano
On January 1, 2016, Hyperion imaged the massive methane leak in the Aliso Canyon region of California. David Thompson’s (JPL) algorithm detected the methane leak within the Hyperion data and showed a pronounced plume trending to the south. Since then, six additional acquisitions have been made, thanks to EO-1’s ability to rapidly schedule, reorient satellite attitude, and quickly process and distribute the data.

</table>
This figure shows the trending of the lunar calibration data over the mission duration. The plot shows that, except for the shortest wavelength in the VNIR focal plane (\(457.34\)), the Hyperion data are stable to within \(\pm 1.5\%\). The data have been normalized to the first acquisition point, and are expressed as percent change from the beginning.
Some bands show signs of phase angle dependencies, e.g. 569, 660, 793, 864 and 1648 nm.

SUMMARY: The ROLO model provides a convenient avenue to conduct overall trending of instrument performance. But the ROLO model is unable to characterize individual detectors.
EO-1 ran out of orbital maintenance fuel in February 2011, when the Mean Local Time (MLT) was 10:00 AM. Since then it has been drifting lower in orbit and earlier in overpass time. EO-1 will reach 8:00 AM MLT by October 2016.
Solar Zenith Angle at EO-1 Overpass

SZA depends on overpass time, latitude, and date. The larger SZAs occurring in 2016 have already been experienced by EO-1 in previous years (at higher latitudes and during winters).
For 40°N in 2016, approximately 60% of the time the SZA at EO-1 overpass time is within the previously experienced SZA range for that latitude.
EO-1 Flight Systems

• Health and Safety of spacecraft (S/C) and subsystems continuing nominal operations
• Power Systems are working nominally
  – After performing a cycle of VT changes to help condition the battery for longer use (improves state of charge, speed of charge and differential voltage), the EO-1 VT is now set to a VT level of 4.5
• Instruments performing nominally
  – Solar and Lunar Calibrations routine including slow scan Hyperion and a negative phase angle lunar calibration to aid Landsat-8 in calibration
• No Life Limiting items identified that would prohibit passivation
EO-1 Mission Enhancements

• The EO-1 mission is out of usable fuel since February 2011 but attitude control system (ACS) fully functional
  – The spacecraft is no longer tasked to perform MLT maintenance burns (inclination burns).
• With a transition from MOPSS (old) to ASPEN (new) and CMS (old) to SCP (new) mission planning systems, the FOT couldn’t initially perform Delta-V maneuvers.
• The FOT created procedures and implemented a way to perform Delta-V maneuvers on the new mission planning systems to perform debris avoidance maneuvers.
EO-1 Mission Enhancements

• EO-1 Lunar Calibration Modifications
  – EO-1 FOT created a way to perform a single scan Hyperion centered lunar calibration
    • This calibration is performed prior to a positive phase nominal 4 scan lunar calibration with ALI and Hyperion
  – Removed all atmospheric corrector (AC) commands and reduced the nominal 5 scan positive phase lunar calibration to a nominal 4 scan positive phase lunar calibration (removed all AC scans/commands).
  – Conducted negative phase lunar calibrations in conjunction with Landsat-8
EO-1 Debris Avoidance Maneuver

• The EO-1 spacecraft had a close approach with a (FENGYUN 1C DEB) on 5/10/2014 at 17:57:40 GMT
  – Miss distance of ~167m

• The EO-1 FOT team worked with ESMO and CARA to plan and perform a 10 second Delta-V maneuver on 9 May 2014 at 13:30 GMT.
  – The Burn was successful, the spacecraft thrusters fired for the full 10 seconds.
EO-1 Recent Anomalies

• All Anomaly Reports available at https://eo1.gsfc.nasa.gov/
EO-1 Orbital Information

- EO-1 Orbit Information on 03/13/15 00:00:00z
  - Semi-major Axis = 7065.655 Km
  - Eccentricity = 0.000545
  - Inclination = 97.936 Deg
  - RAAN = 338.705 Deg
  - Argument of Perigee = 50.504 Deg
  - True Anomaly = 137.525 Deg
  - Altitude at Apogee = 691.366 Km
  - Altitude at Perigee = 683.669 Km
Earth Observing-1 Inclination Status for the MOWG

FreeFlyer Plot

EO1.BLZI (deg) vs EO1.ElapsedDaysFromEpoch(EO1.StartTime) (days)
The ALI SNR is inherently 6 to 10X (~800%) that of ETM+.

The ALI signal at 8 AM always exceeds 50% of the 10 AM.

ALI SNR at 8 AM will be 3 to 5X better than that of ETM+ at 10 AM.

EO-1 will not reach an 8 AM crossing time until October 2016.

ALI data taken at an 8 AM equatorial crossing time is valuable in spite of the decline in SNR.

Signal (i.e. solar irradiance) is a function of the cosine of the solar zenith angle (SZA).

Future NASA Budget Outlook

• Full year of operations during FY2016 with decommissioning starting October 2016 has been authorized

• Phase F report for decommissioning management starting October 2016 submitted to NASA Headquarters 31 March 2016
Backup
EO-1 New Ground Stations

– EO-1 Flight Operations Team (FOT), Earth Observing Systems (EOS) Data and Operations System (EDOS), Near Earth Networks Services (NENS), Universal Space Network (USN), and Wallops and White Sands scheduling personnel worked to switch from PF1/PF2 to Northern Alaska ground stations
  • testing of S-band uplink/downlink, X-band downlink, and telemetry tracking for new ground stations in northern Alaska designated USAK-02/03/04
  • coordination of firewall rule updates
  • conducting test passes over the new ground stations
  • implementation of modifications to the ground and flight software to point the satellite antenna at the correct locations
  • analysis of the command link, telemetry receipt, science data capture, and ranging/tracking data files for operational readiness
The alternative way to understand and assess the stability of Hyperion is to perform a SBAF time series study.

- Figure shows the SBAF (OLI/S2) stability is better than 0.1% for last 12 years (except for blue band).
- This would also mean that constraint on simultaneous image pair based cross calibration can be relaxed to take advantage of the long term stability of the site,
- The stability of Landsat 8 and Sentinel-2 reduces the impact of an eventual loss of Hyperion.
