BioSentinel: Enabling CubeSat-Scale Biological Research Beyond Low Earth Orbit

Matt Sorgenfrei, PhD
Intelligent Systems Division
NASA Ames Research Center
BioSentinel

Outline

• Introduction
• Mission Overview
• Spacecraft Concept
• Design Challenges and Future Work
INTRODUCTION
A Unique Launch Opportunity

- NASA Advanced Exploration Systems (AES) is sponsoring 3 secondary payload slots on the first flight of the Space Launch System
- Secondaries will be deployed into a heliocentric orbit after separation of Orion CEV
- Baseline design constraints allow for 6-cube volume and 14 kg mass
3 Distinct Missions

- Marshall Spaceflight Center, Jet Propulsion Laboratory, and Ames Research Center are supplying spacecraft.

- MSFC NEOScout will inspect a NEO target, JPL LunarFlashlight will explore permanently shadowed craters on the moon, and Ames BioSentinel will characterize radiation environment.
Where CubeSats Haven’t Gone Before

• Exact deployment orbit of secondaries still being characterized
  – Possible requirement for ΔV maneuver
• Will likely be Earth-trailing, heliocentric orbit
• Far outside the orbits typically occupied by CubeSats

A representative orbit that the BioSentinel spacecraft could occupy
Valuable Access to the Space Environment

- The space radiation environment cannot be duplicated on Earth, making research into its effects challenging
- BioSentinel will measure a specific type of DNA damage resulting from exposure to this environment
- Laboratory-engineered yeast cells will sense and repair direct damage to their DNA (in the form of double-strand breaks)
  - Gene repair will initiate cell growth in microwells within payload volume

Representative yeast growth cells similar to those that will be used in BioSentinel
Ionizing radiation presents a major challenge to human exploration of deep space
- Specific deleterious effects of long-term exposure are unknown

Challenging to replicate deep space radiation environment on Earth, particularly with SPEs

Eukaryotic yeast cells are a valuable analogy for future manned missions

BioSentinel will provide insight into shielding strategies and radiation countermeasure development
Building on Ames Heritage

- Ames has previously flown biologically-focused CubeSats with the GeneSat, PharmaSat, and O/OREOS missions
- Spacecraft make use of miniaturized life support systems to allow for growth of cells in microgravity environment
- BioSentinel will leverage this heritage to build three separate payloads:
  - Flight payload, module that can be integrated on station, and ground control

The PharmaSat 3U spacecraft, which carried a microwell and fluidics system similar to that which will be used in BioSentinel
Bonus Payload: Radiation Sensor

- In addition to biology payload, BioSentinel will fly a stand-alone radiation sensor to provide direction measurement of galactic cosmic radiation.
- Requires linear energy transfer detection and integrating dosimetry (TID) capability.
- Future design work related to type of sensor and implementation, integration with spacecraft bus.
- Collaboration with JSC RadWorks group.

The TimePIX linear energy transfer detector chip.
A Wide Range of 6U “Firsts” for Ames

- First 6U CubeSat to fly beyond LEO
- First CubeSat to combine both active attitude control and a biology science payload
- First CubeSat to combine both active attitude control and propulsion subsystems
- First CubeSat to integrate a third-party deployable solar array

Major BioSentinel subsystems shown with rough order-of-magnitude volume budgets
SPACECRAFT CONCEPT
Current design concept for the BioSentinel Spacecraft
Environmental Considerations

• Higher exposure to radiation than experienced by previous CubeSats operating in LEO
  – Approximately 5 kRad totally ionizing dose anticipated
  – Non-destructive single events (such as SEUs) motivate > 20 MeV-cm² tolerance, destructive single events (SELs, SEBs) require > 37 20 MeV-cm² tolerance

• Distance from Earth eliminates use of GPS for position determination, magnetometers for attitude determination, or torque coils/rods for attitude control

• Solar radiation pressure will be largest disturbance torque
Subsystem Considerations

• Deployable solar panels required to generate sufficient power for all subsystems

• Traditional CubeSat S-band/UHF radios insufficient at mission operating orbit
  • X is preferred band (up and down) for deep space missions

• Propulsion required for both detumble and momentum management

• Biology must be maintained at a specific temperature and acceleration range

Candidate components under consideration for the BioSentinel mission
Data Rates Achievable

Rate at nominal mission end (0.43 AU)
Rate at extended mission end (0.7 AU)
Avionics Challenges

• BioSentinel will require a command and data handling (C&DH) system that is much more capable than previously flown in CubeSat-form factor spacecraft
• Simultaneously would like fairly inexpensive development boards for prototyping and testing campaigns
• Radiation tolerance of high importance
  – Radiation-hardened or phase-change memory, watchdogs, multiple or “golden” software loads, etc
• Implications for GNC development strategy: auto-coding vs. hand-coding filers, control schemes, schedulers, etc
A representative mode transition diagram for the BioSentinel mission
DESIGN CHALLENGES/
FUTURE WORK
• Tip-off conditions from SLS are a major unknown
  – Initial body-fixed rates, potential need for a ∆V maneuver
• Tip-off conditions help to define GNC system needs, which will drive other subsystem budgets
• Detailed power budget assessment: ~30 W orbit-average power should allow for radio to be always on
  – As opposed to traditional CubeSat missions in which subsystem cycling sometimes required
• Need to define ground operations strategy
  – DSN likely the most feasible approach, issues with availability and cost
  – 34m likely acceptable for majority of mission life, larger array required at end of mission
QUESTIONS?

MATTHEW.C.SORGENFREI@NASA.GOV
BACK-UP SLIDES
Location in Lunar Centered Space

Now that ICPS trajectory has been recreated, propagate forward in time:

- ICPS appears to coast out into interplanetary space following its lunar flyby.
- A cubesat deployed with +/- 2 m/s ejection speed as early as 1 hr after TLI will also escape into interplanetary space but distance from Earth will vary.
Radiation Environment

- Shielded solar proton spectrum
- Total Ionizing Dose

</table>
• **Momentum Management**
  − No torque rods available
• **Prop is typical solution**
  − Tanks hard to accommodate
  − Hazardous fuels hard to accommodate
  − Need small impulse bits
  − Need low power for valve actuation
• **Possible use of solar sailing**
  − Alternate pointing direction to counter momentum buildup
• **Almost all are fairly low TRL**

CFE/CFS Layered Architecture

- Each layer “hides” its implementation and technology details.
- Internals of a layer can be changed -- without affecting other layers’ internals and components.

- Enables technology infusion and evolution.
- Doesn’t dictate a product or vendor.
- Provides Middleware, OS and HW platform-independence.
