</tbody>
</table>
Structural Differences Between Rockets and Airbreathers

- **Tanks**
  - Cylindrical, since vehicle is weight sensitive and volume insensitive

- **TPS**
  - Driven by descent
  - Low heat load due to short ascent

- **Leading edges**
  - Blunt, due to desire for descent drag
  - High heat flux

- **Structure**
  - Lightly loaded wings
  - Propulsion and airframe not highly integrated

- **Tanks**
  - Conformal, since vehicle is drag, and thus volume, critical

- **TPS**
  - Driven by ascent
  - High heat load due to long ascent time

- **Leading edges**
  - Sharp, due to low drag, low thickness/chord
  - Severe heat flux

- **Structure**
  - Highly loaded wings (some air breathers)
  - Hot wings and control surfaces due to thin cross sections and high heat flux/load
  - Propulsion and airframe highly integrated

Drag is the big driver for hypersonics
Hypersonic Vehicles

♦ Goal
  • Speed
  • Range

♦ Propulsion
  • Provide thrust

♦ Aerodynamics
  • Provide lift
  • Control the vehicle
  • Minimize drag

♦ Structures and materials
  • Minimize weight
  • Survive required mission
    ▪ Thermal / structural
    ▪ Acceleration
    ▪ Acoustic / vibration
    ▪ Environmental

♦ Weight reduction
  • High specific strength materials (high strength, low density)

♦ Drag reduction
  • Thin vehicle cross-sections
    □ Insulating a cold structure adds cross-sectional area
  • Sharp leading edges
  • Smooth surfaces

Hot structures
Flight Vehicle Thermal Management

- **Hot Structure**
- **Active Cooling**
- **Ablators**
- **Insulation**
- **Heat Sink**
- **Exposure Time, hr**
- **T, K**
- **Apollo**
- **Mercury**
- **Shuttle**
- **x-15**
- **SR-71**
History Shows That New Material Systems Help Enable the Vehicle

- Titanium
- Inconel
- Ceramic tiles and blankets
- C/C leading edges
- Ceramic Matrix Composites (CMC’s)
CMC’s are the material system that will provide the required strength at elevated temperature.
CMC Hot Structure Weight Savings

♦ Space Shuttle Orbiter Body Flap (AIAA-1983-913)
  ● Baseline 1460 lb, insulated cold structure
  ● ACC body flap 1207 lb (253 lb, 17% weight savings)

♦ HSR (NASA High Speed Research program) SiC/SiC Combustor Liner
  ● Projected 30% weight savings
  ● Reduced NOx and CO emissions due to higher temp

♦ X-38 C/SiC Hot Structures
  ● Bearings 50% lighter weight than traditional bearings
  ● Body flap 50% less than insulated cold structure (5.25 ft x 4.6 ft, 150 lb)
  ● Rudder (different design temperature)
    ▪ PM-1000 with Ti inner structure and insulation: 133 lb with growth factor of ~ 5%
    ▪ CMC: 97 lb with higher growth factor (27% weight savings)

♦ Aircraft brakes
  ● 500-1000 lbs per plane weight savings

♦ Actively cooled CMC combustor (French study, AIAA-2011-2208)
  ● 30% weight savings over metallic

Rule of thumb, ~ 25% weight savings with CMCs
Key Point – Drag Reduction

♦ Reentry vehicles (most of our prior experience), want drag to reduce velocity as they reenter.

♦ Cruise vehicles must minimize drag as they cruise through the atmosphere.
  - Surface and cross-section

♦ Hot structure is the preferred approach (rather than TPS over cold structure)
  - Large, smooth, hot airframe has not been addressed
A Few General Thoughts

♦ Weight is always critical

♦ High risk ≠ high payoff
  ● Might be, but not an automatic

♦ Requirements have a significant impact on TRL
  ● Number of cycles
  ● Mechanical loads
  ● Pressure (oxidation)
  ● Heat flux
  ● Etc.

♦ Thinking of how much it will cost to develop a technology is often a better gage of how far away we are than asking how long it will take

TRL = f(requirements)
Can’t change requirements and expect to keep TRL the same
Leading Edges

♦ **State of the art**
  - Space shuttle orbiter RCC
  - Hyper-X coated C/C
  - HTV-2 oxidizing C/C

♦ **Requirement**
  - Multi-use
  - Light weight
  - Durable
  - Sharp

♦ **Technical challenges**
  - Manufacturing
  - Life
  - Thermal stress
  - High heat flux / temperature
  - Environmental durability
Typical Ascent Leading-Edge Heat Flux for SSTO

In comparison, Shuttle Orbiter leading edge ~ 80 W/cm², CEV heatshield ~ 800 W/cm²
Leading-Edge Radius Effect on Stagnation Heat Flux

Heat flux, $\alpha \frac{1}{\sqrt{\text{radius}}}$

1 cm radius, 500 W/cm²
Sharp leading edges produce intense, localized heating.
Active Oxidation of Si-Based Materials

♦ Transition from passive to active oxidation function of
  - Temperature
  - Oxygen partial pressure
  - Plasma speed
  - Degree of dissociation

♦ Destroys protection of Si containing system
  - C/SiC
  - SiC/SiC
  - Coated C/C
  - UHTC
  - … etc.

Arc-jet test of DLR C/C-SiC for X-38 at NASA JSC

Arc-jet test of MT Aerospace C/SiC in the German PWK2 facility
Heat-Pipe-Cooled Leading Edges

Heat pipe results in an isothermal leading edge.
NASP Heat-Pipe-Cooled Wing Leading Edge

Leading Edge

Carbon/carbon (C/C) structure

Mo-Re container

Challenges
- Material compatibility, f(t,T)
- Thermal stresses

Mo-Re embedded in C/C
- Li working fluid
- D-shaped heat pipes
Control Surfaces

♦ State of the art
  ● Space shuttle orbiter (insulated)
  ● X-38 (CMC hot structure)
  ● HTV-2 C/C
  ● NASA X-37 evaluated C/C and C/SiC

♦ Requirement
  ● High strength at elevated temperature
  ● Light weight

♦ Technical challenges
  ● Volume constrained
  ● Manufacturing
  ● Recession / stressed oxidation
  ● Thermal stress
  ● High heat flux / temperature
  ● High heat load
  ● Heat conduction into vehicle / insulation
Types of Control Surfaces

♦ Insulated
  • Suitable for very large structures
  • Minimal thermal expansion issues
  • Heavy
  • Little thermal margin
  • Thick cross section

♦ Hybrid
  • Affordable manufacturing for large structures
  • May not require TPS on upper surface
  • Thermal growth mismatch between metal/PMC and CMC
  • Weight increase 30-40% over all CMC

♦ Hot Structure
  • Lowest weight and thin cross section
  • Minimal thermal expansion mismatch problems
  • Thermal margin
  • High manufacturing/tooling costs for box structure
  • Challenging for very large structures
X-38 Hot Structures

♦ **C/SiC nosecap, skirts & chin panel**
  - Nosecap provided by DLR (Germany)
  - Nose skirts (2) provided by Astrium (Germany)
  - Chin panel provided by MT Aerospace
  - Nose assembly has undergone full qualification (qual units)
    - Vibration
    - Thermal (radiant)
    - Mechanical

♦ **C/SiC body flaps**
  - Provided by MT Aerospace
  - Qualified for flight
Dutch Space Metallic Hot Rudder

♦ X-38 hot rudder

- Fabricated and tested a PM-1000 rudder to 2192°F (1200°C) in 1 yr
- Requirements changed
- Qualified Ti/ceramic tile rudder (1 yr)
- Planned Ti/CMC rudder for crew return vehicle (CRV)
MT Aerospace Integrated Fabrication Approach

♦ Advantages
  ● Fewer joints
  ● Better mechanical performance

♦ Disadvantages
  ● Complex tooling and associated fabrication expense
  ● Risk of damage during fabrication

♦ Fabrication
  ● 2-D prepreg of carbon fabric
  ● Cured and pyrolyzed
  ● Further densified with CVI SiC
  ● No fasteners (less mass)
Acreage TPS / Hot Structure Aeroshell

♦ State of the art
  ● Ceramic tiles and blankets
  ● Ablators
  ● Oxidizing C/C hot structure

♦ Requirement
  ● Durable
  ● Thin cross section
  ● Smooth OML
  ● Insulate interior (keep the heat out)

♦ Technical challenges
  ● Manufacturing
  ● Durability
  ● High temperatures
  ● Large heat load due to extended duration flight
  ● High temperature insulation
  ● Combined loads
Trade studies required on how to best meet requirements and optimize performance – need to keep trade space wide open.
Windward CMC Standoff (Shingle) TPS (Snecma, IXV)

- **Total mass of CMC shingle system**
  - ~3 lb/ft² (15 kg/m²) (very much f(req.))
  - Not optimized

- **Attachment system design**
  - Mechanically attach panel to structure
  - Transfer loads from panel to structure
  - Enable expansion differences
  - Prevent large OML deformation through sufficient stiffness
  - Participate in thermal protection of structure
  - Easily replaced

**Sealing approaches**
- C/SiC pressure ports
  - 10 windward

**Attachment approach**
- Curved C/SiC panel
  (IXV side panel)
Internal Insulation

- Light-weight
- Flexible
- Non load-bearing
- Non-oxidizing
- Reflective foils or no foils
- High volumetric heat capacity
- Low effective thermal conductivity
- Capable of long duration flight at elevated temperatures
Propulsion Structures

♦ State of the art
  ● Passive heat sink
  ● Actively cooled superalloy

♦ Requirement
  ● Light weight
  ● High heat flux/temperature
  ● Reduced fuel

♦ Technical challenges
  ● Hermetically sealed CMC with no tubes
  ● Manifold

♦ MBDA (France)
  ● Fuel cooled CMC combustor
  ● No metallic tubes

♦ NASA & AF (Teledyne Scientific)
  ● Last funding several years ago
  ● No tubes

♦ NASA (HyperTherm)
  ● SiC/SiC with refractory metal tubes
Passive CMC Combustor Material Evaluation

- **Simulated Mach 6 conditions**
  - Actual flow velocity ~ Mach 2
  - $q = 1000$ psf (479 hPa)
  - $H = 793$ Btu/lb (1.846 MJ/kg)

- **Hydrogen fuel**

- **4 tests**
  - M ~ 6 enthalpy
  - 20 sec tare (no fuel)
  - 3 x 44 sec fueled tests

- **C/C-SiC Panel #1 Post Test**
  - 4 tests
  - M ~ 6 enthalpy
  - 20 sec tare (no fuel)
  - 3 x 44 sec fueled tests

**Flow**

**DLR C/C-SiC test article**

**C/C-SiC hot surface, post test**
Design and Manufacturing

- **Design for manufacturing**
  - Involve manufacturers in the process
  - Don’t “throw it over the wall”

- **Properties in a complex structure are often different than material test coupons**

- **Attachments and joints**
  - Different material systems
    - Severe thermal gradients in multiple directions
  - Mechanical loads

- **Metrology often “required” for accurate fabrication and assembly**
  - Optical / laser devices
  - Accuracy to < 0.001 in., f(size)

- **TRL = f(requirements / loads)**
  - Can’t change the requirements / loads and keep the TRL

- **Affordable, robust, & simple**

A state-of-the-art material is not the same thing as a state-of-the-art structure

Big difference!
How do we qualify the vehicle for flight?

- We are unable to test many components in relevant, combined loads, environments (even small scale)
  - Thermal, mechanical, plasma, shear, oxygen partial pressure, vibration and acoustic, etc.
  - Apply appropriate boundary conditions over entire structure
  - Thermal gradients (spatial and temporal) from boundary layer transition

- **Thermally generated stress ≠ mechanically generated stress**

- Extensive testing is required
  - Performance testing and benchmarking for analyses

Building block approach

- Extensive testing is required
  - Performance testing and benchmarking for analyses

Test as much as you can, and still include adequate margins for uncertainties.
Thermal-Structural Analysis

- **Adequate material properties**
  - $f(T)$, $f($processing$)$, etc.
  - Adequate quantities (shape of curve and statistics)
  - Capture non-linear behavior

- **Boundary conditions**
  - Thermal, mechanical
  - Boundary layer transition

- **Mesh convergence**

- **Local / global models**
  - Apply global loads to local models

- **Mechanical / thermal stresses**

- **Factors of Safety (FOS)**

- **Failure modes**
  - Biaxial stress interaction
  - Thermal $\neq$ mechanical failure
Thermal Stress

- **Generated by restrained thermal growth**
  - Temperature gradients and / or different materials (CTE)

- **Very different from mechanical stresses**
  - Driven by thermal gradients, not just high temperatures
  - Thicker structure can make it worse
  - Structurally connected, dissimilar materials, also drive thermal stress

- **Complicated by different materials, 3-D thermal gradients, moving hot spots, asymmetric heating, etc.**

Thermal stress failure due to differential thermal expansion at uniform temperature

SR-71 grows ~ 3 in. during flight

Thermal stress must be understood and accurately tested and modeled
Concluding Remarks

♦ Reduction of weight and drag are key for all hypersonic vehicles

♦ A state-of-the-art material is not the same thing as a state-of-the-art structure

♦ TRL = f(requirements / loads)
  ● Can’t change the requirements / loads and keep the TRL

♦ Long duration flight results in high integrated heat loads that impact design

♦ Hot structure should be traded versus insulated (TPS) cold structure
  ● Open up the trade space

♦ Thermal stress must be understood and accurately tested and modeled
