Texas Disasters II

Utilizing NASA Earth Observations to Assist the Texas Forest Service in Mapping and Analyzing Fuel Loads and Phenology in Texas Grasslands

Michael Brooke (Project Lead)
Meredith Williams
Teresa Fenn
Objective

Assist the Texas Forest Service in **Mapping** and **Analyzing** Fuel Loads and Phenology in Texas Grasslands
Study Area

S

Study Period

January 2000 - November 2015

Environment

Texas vegetation are highly susceptible to wildfires. The risk of severe wildfires related to weather phenomena has increased due to climate change and recent development.

The combination of El Nino and La Nina events, which can lead to more intense fire seasons.

The Texas Forest Service is tasked with evaluating and reducing potential fire risk.
Increased Biomass

Increased Fuel Loads
Background

- In 2011, 31,453 wildfires burned 4 million acres & destroyed 2,947 homes
- 80% of wildfires occur within 2 miles development areas
- Six of the 10 largest documented wildfires in state history occurred in April 2011

NDVI

Normalized Difference Vegetation Index

NDVI = (NIR - Red)/(NIR + Red)

Measure plant productivity based on greenness of vegetation

\[
\frac{(0.50 - 0.08)}{(0.50 + 0.08)} = 0.72 \\
\frac{(0.4 - 0.30)}{(0.4 + 0.30)} = 0.14
\]

Methodology

Precipitation
What precipitation conditions create hazardous wildfire conditions?

Phenology
What phenological parameters do different areas have in common?

Soils
Do soil types drive the swings in phenology?
Methodology
Climatology

Average Precipitation – 28-40 in/year
2010 – 4 inches above normal
2011 – 10 inches below normal
Methodology

Phenology

- NDVI and DOY averaged for study period
- Median filter applied to DOY
Methodology

Phenology

Parameters from each year were compared to the mean.
Methodology

Phenology

Parameters from each year were compared to the mean.
Methodology

Phenology

Parameters from each year were compared to subsequent years.
Methodology
Phenology – Large Integral NDVI

Results

Selected phenology parameters for high-risk area

- NDVI values scaled by 10,000
- **2010** considerably more productive than mean
- **2011** considerably less productive than mean
Results

Selected phenology parameters for high-risk area

- Day of year values
  - **2010** had a much longer growing season than mean
  - **2011** had a much shorter growing season than mean
Results

Selected phenology parameters for high-risk area
Results

• If by mid-May the NDVI value has not reached close to 0.6 within the majority of the High-Risk Area, there is a greater risk of wildfires.

• If the previous year had a growing season near 200 days long combined with a max NDVI of 0.7, the fuel load may contribute to more severe wildfires.
Conclusion

• There is a high-risk area within the study area that has an enhanced phenological response to both wet and dry years relative to the surrounding area.
• This high risk may be driven more by soil type than climate (though the latter does contribute to risk).
• This area should experience greater risk for large, damaging wildfires given a La Nina climatic event after a previously lush year (e.g., 2011 versus 2010).
• As yearly climate swings grow more pronounced and growth continues in the area, this risk may escalate.
Limitations and Future Work

• Look at all points in the growing season “NDVI” curve
• Consider temperature on a monthly basis
• Timing of first freeze
• Look at current El Nino to assess wildfire risk and impacts of this climatic event
• Assess alternative MODIS/Landsat data fusion methods (e.g., STAR FM)
