ASHE ALGORITHM
The Aerosol Single scattering albedo and Height Estimation (ASHE) algorithm was first introduced in Jeong and Hsu (2008) to provide aerosol layer height and single scattering albedo (SSA) for biomass burning smoke aerosols. By using multiple satellite sensors synergistically, ASHE can provide the height information over much broader areas than lidar observations alone. The complete ASHE algorithm uses aerosol data from MODIS or VIIRS, OMI or OMPS, and CALIOP. A simplified algorithm also exists that does not require CALIOP data as long as the SSA of the aerosol layer is provided by another source. Several updates have recently been made: inclusion of dust layers in the retrieval process, better determination of the input aerosol layer height from CALIOP, improvement in aerosol optical depth (AOD) for nonspherical dust, development of quality assurance (QA) procedure, etc.

Method
The ASHE algorithm utilizes the sensitivity of UAVI to AOD, SSA, and aerosol height. The SSA or height can be retrieved if the other two parameters are constrained. Thus AOD and aerosol height should be constrained for retrieving SSA, and AOD and SSA should be constrained for aerosol height.

Case study

EVALUATION
The ASHE algorithm has been evaluated for wildfire smoke aerosols over North America, biomass burning smoke aerosols over Southeast Asia, and Saharan dust over the Atlantic Ocean. In particular, a thorough assessment was made for the smoke aerosols over Southeast Asia based on comprehensive ground-based observations, including MPLNET and AERONET during the 7-SEAS/BASELINE field campaign.

Conclusions
• Aerosol layer height can be retrieved over broad areas by synergistic use of MODIS/VIIRS, OM/OMPS, and CALIOP observations.
• The algorithm is stronger for large-scale, single-layer aerosol events than small-scale, multilayer cases.
• The algorithm can be applied without CALIOP observations with a decrease in performance but an increase in spatiotemporal coverage.
• For the simple algorithm, a SSA climatology derived from the ASHE algorithm and/or AERONET can be used to constrain the SSA for different aerosol types over the globe.
• In addition, the ASHE-retrieved SSA can potentially be used in the Deep Blue algorithm to constrain aerosol model for better performance.
• Currently, only one smoke and one dust aerosol models are used; more sophisticated aerosol models are planned to be included for applications to other regions.
