The Bioculture System is a cell biology research platform for the International Space Station that supports short- and long-duration studies involving the culture of living cells, microbes, and tissues in the unique microgravity environment of spaceflight.

Microgravity affects most organ systems of the body. Research conducted in space is essential for us to understand the biological consequences of these effects and to develop countermeasures—procedures, drugs or devices—to protect health. Gaining a deeper understanding of the mechanistic role of gravity in the regulation of biological systems is a high priority research goal for NASA. The Bioculture System supports this goal by broadening the scope of microgravity experiments available to scientists.

Based upon the prior generation Cell Culture Module that flew on 21 space shuttle missions, the new system houses ten independent Cassettes, each of which may run for months aboard the station—far longer than the previous shuttle mission limit of two weeks.

Academic and commercial researchers may use the Bioculture System to study a wide range of biological processes in microgravity that are relevant to human health. These experiments can help us understand how gravity affects the physiology, biochemistry, genetics and gene expression of living cells, tissues and microbes. For example, cells and tissues cultured during spaceflight may be characterized using various “omics” techniques, used for drug discovery and countermeasure analyses, or used to study infectious disease processes. Other possible applications, which are not limited to these examples, include spaceflight studies of tissue engineering, regeneration, and wound healing.

Each Cassette contains a fluidics flow path and biochamber for perfusion-based culturing and is divided into two independent temperature zones; an incubation zone for the biochamber, and
an insulated cold zone for culture medium or other temperature-sensitive solutions and collected specimens. Temperature control is independent for each cassette and the gas supply is shared. A power and command module supplies power and data ports to each Cassette.

The first Bioculture System will fly to the station aboard the SpX-5 mission in 2014. Station crew will install it in the U.S. Destiny module. Once installed, the system will be monitored and commanded by ground staff at NASA’s Ames Research Center, Moffett Field, Calif.

The goals for the first flight are to validate system performance and demonstrate manual crew operations. The study will involve the culture of cardiomyocytes and adipose tissue-derived stem cells for a period of up to 30 days. The system will be available for use by researchers after the validation study is completed, starting with the SpX-7 mission in 2015.

The Bioculture System is being developed at Ames under the leadership of the Ames Research Center International Space Station Utilization Office and within the Space Biosciences Division. Tissue Genesis Inc., Honolulu, Hawaii, is performing the hardware development. Lockheed Martin is providing science, engineering, and mission operations support.

This project is funded by the International Space Station Program at NASA’s Johnson Space Center, Houston, and the Space Life and Physical Sciences Research and Applications Division within the Human Exploration and Operations Mission Directorate at NASA Headquarters.
