Space Radiation Risks

- **Carcinogenesis (morbidity and mortality risk)**
- **Acute and Late Central Nervous System (CNS) risks**
  - immediate or late functional changes
- **Chronic & Degenerative Tissue Risks**
  - cataracts, heart-disease, etc.
- **Acute Radiation Risks** – sickness or death
Unrejoined chromosome breaks after low- and high-LET radiation exposure in human fibroblast cells. Wu et al. 2002
Combined effects of radiation and spaceflight factors

**Experimental design**

- Exposure pre-flight
- Exposure during flight
- Exposure post-flight

**Effects**

- Synergistic - enhanced
- Additive - same
- Antagonistic - reduced
Chromosome aberration frequencies in pre- and post-flight astronaut lymphocytes irradiated in vitro with low-LET radiation (Wu et al. Phys. Med. 2001)

Mission: STS-103

Duration: 8 days

Blood draw schedule:
10 days before launch, JSC, kept at 4 C for 1 day before exposure
0 days after landing, KSC, kept at 4 C and received next day. Kept at 4 C before exposure
14 days after landing, KSC, kept at 4 C for 1 day before exposure

Irradiation: Whole blood was irradiated to gamma rays

Procedure: Whole blood was stimulated to grow with PHA in growth medium and chromosomes were collected following standard procedures.

Chromosome analysis: Chromosomes #1 and #5 were painted.
Wu et al. 2001

- Post-flight blood was collected 3 days after landing

- Samples were exposed to X-rays
Chromosome aberrations in lymphocytes induced by beta particle exposure in flight (Bender et al. Rad. Res. 1967, 1968)

**Gemini-3**

- Chromosome deletion
  - Ground: Blue
  - Flight: Pink
  - Dose (Gy) vs. Frequency

- Rings and dicentrics
  - Ground: Blue
  - Flight: Pink
  - Dose (Gy) vs. Frequency

**Gemini-11**

- Chromosome deletion
  - Ground: Blue
  - Flight: Pink
  - Dose (Gy) vs. Frequency

- Rings and dicentrics
  - Ground: Blue
  - Flight: Pink
  - Dose (Gy) vs. Frequency

Mission Duration
- Gemini-3: 4 hr 52 min
- Gemini-11: 4 day 1 hr 56 min

Temperature
- Gemini-3: Ambient
- Gemini-11: Refrigerated-ambient
Cell: Human fibroblasts
Exposure: X rays. Ground – pre-flight
End point: DNA repair in flight
Cell: B. subtilis (Bacteria)
Exposure: UV. Ground – pre-flight
End point: Survival
FIG. 3. Survival of rad54-3 yeast cells after β-particle exposure. Solid symbols: incubation at 22°C (permissive temperature); open symbols: incubation at 37°C (restrictive temperature). Circles: incubation under microgravity; squares: ground control. The error bars indicate standard errors for dose (x axis) derived from multiple measurements (see the Materials and Methods section) of the same source. Lines drawn are only intended to guide the eye and do not imply a functional dependence.
Chromosome aberrations in astronauts’ lymphocytes from direct exposure to space radiation

RBE for CA as a function of LET showing a similar trend as the quality factor
## Results for ISS Biological Dose Equivalent (BDE) Defined by Eq. (2) and Physical Dose Estimates

Micro-7 Project Objectives

Aim #1. Investigate changes of miRNA and RNA expression in G1 human fibroblast cells in space.

Aim #2. Investigate cellular responses to bleomycin-induced DNA damage in G1 human fibroblast cells in space.

Aim #3. Detect the DNA damage in cells from direct exposure to space radiation.
Confluent human fibroblast cells were cultured in BioCells. The cells were kept in CGBA on ISS at 37 C.
**Flight Schedule**

4/18/14 – Cells were launched to ISS on board SpaceX-3.

4/22/14 – Cells were transferred to a 37 C incubator.

4/25/14 – Cells were fixed for RNA and miRNA analysis (Day 3).

4/25/14 – Cells were treated with bleomycin (1 μg/ml) (Day 3).

5/6/14 – Cells were fixed for RNA and miRNA analysis (Day 14).

5/20/14 – The fixed samples returned to JSC.
Does spaceflight influence RNA and miRNA expression in non-dividing cultured cells?

The direct interaction analysis showed several projected networks with c-Rel, ETS1 and Ubiquitin C as key factors. Several genes showed direct interactions with miRNAs that were found to be altered in simulated microgravity environment. Seven genes cyclin E2, HMGA2, EGR2, ZNF145, Ubiquitin C, ETS1 and c-Rel were subjected to validation analysis using Quantitative Real-time PCR.

Spaceflight or simulated microgravity influences gene and miRNA expression in proliferating cells
Microarray Results – Day 3 and Day 14

Number of genes having significant expression changes in the flight samples in comparison to the ground controls on Day 3 and Day 14
Microarray Results – Day 3 and Day 14 (Continued)

- The Day 3 data indicated activation of NFkB and other growth related pathways involving HGF and VEGF in the flown cells.

- The results are consistent with faster cell proliferation of the cells in space as measured by the percentage of ki-67 positive cells.
Microarray Results – Day 3 vs. Day 14

Number of genes having significant expression changes in the Day 3 sample in comparison to the Day 14 sample.

The Day 3 cells still grew slowly even when the majority of the cells were in G1 phase.
No significant changes in the cytoskeleton between ground and flown cells

Ground

Flight

Cells were stained with $\alpha$-tubulin antibodies
Summary 1

• On Day 3, both the flown and ground cells were still proliferating slowly even though they were confluent, as measured by the expression of ki-67 positive cells, and the cells in space grew slightly faster.

• Gene and miRNA expression data for Day 3 indicated activation of NFkB and other growth related pathways involving HGF and VEGF in the flown cells.

• On Day 14 when the cells were mostly non-dividing, the gene and miRNA expression profiles between the flight and ground samples were indistinguishable.

• Comparison of gene and miRNA expressions in the Day 3 versus Day 14 samples revealed that most of the changes observed on Day 3 were related to cell growth for both the flown and ground cells.
Do microgravity and other spaceflight factors affect cellular response to DNA damages (by space radiation)?

No difference in the expression of DNA damage response genes was found between the flight and ground samples.
Summary 2

• Images of the 3-dimensional $\gamma$-H2AX foci were captured with a laser confocal microscope. Quantitative analysis revealed a small fraction of foci that were larger and displayed a track pattern in the flight samples in comparison to the ground control.

• Damage in the DNA from bleomycin treatment was measured by the phosphorylation of a histone protein H2AX ($\gamma$-H2AX), which showed slightly more foci in the cells on ISS than in the ground control. The difference was likely caused by the slightly faster growth of the cells in space.

• Although a number of genes, including CDKN1A and PCNA, were significantly altered in the cells after bleomycin treatment, no significant differences in the expression profiles of DNA damage response genes were found between the flight and ground samples.
Conclusions

• In true non-dividing human fibroblast cells, microgravity in space has little effect on the gene and miRNA expression. Gene and miRNA expression changes were observed in cells that were confluent, but still proliferating slowly. The faster growth in the flown cells was associated with the activation of NFkB pathways which triggers the expression of several growth factors and the suppression of the cell cycle checkpoint.

• The difference in γ-H2AX formation in response to bleomycin-induced DNA damage between flight and ground was due to the faster growth rate of the cells in space, but spaceflight did not affect the response of the DNA damage response genes to bleomycin treatment.
