Thermal Barrier Coatings (TBCs) Provide Thermal Protection for Gas Turbine Engine Components

- Ceramic oxide TBCs, e.g., yttria-stabilized zirconia, can increase engine temperatures, reduce cooling, lower emission, and improve engine efficiency and reliability.

- TBCs provide thermal protection by sustaining a thermal gradient between the TBC surface and underlying metal component.
Motivation for Evaluating Combined TBC + Air-Film Cooling

- TBC and air film cooling effectiveness usually studied separately.
- TBC and air film cooling contributions to cooling effectiveness are interdependent and are not simply additive.
- Combined cooling effectiveness must be measured to achieve optimum balance between TBC thermal protection and air film cooling.
Heat Transfer Through Turbine Blade/Vane

Mainstream Gas Flow

$T_{\text{mainstream}}$ → $T_{\text{air film}}$ → $T_{\text{metal}}$

$d_{\text{TBC}}$ → $\Delta T_{\text{surface convection}}$ → $\Delta T_{\text{TBC}}$ → $\Delta T_{\text{backside convection}}$

Cooling effectiveness:

$$\Phi = \frac{T_{\text{mainstream}} - T_{\text{metal}}}{\Delta T_{\text{total}}} = \frac{1}{h_{\text{conv}}} + \frac{d_{\text{TBC}}}{k_{\text{TBC}}} + \frac{d_{\text{metal}}}{k_{\text{metal}}} + \frac{1}{h_{\text{backside}}}$$

- Air film cooling greatly reduces effective $h_{\text{conv}}$, and therefore greatly reduces $\Phi_{\text{TBC}}$
- Air film cooling greatly reduces $q$ and therefore $\Delta T_{\text{TBC}}$

Experimental measurements of combined TBC + air film cooling effectiveness are needed to evaluate TBC/air-film-cooling tradeoffs (Air film cooling carries significant penalty for engine efficiency).
Objectives

- Experimentally map effectiveness of air film cooling on TBC-coated surfaces.
- Examine changes in cooling effectiveness as a function of:
  - Mainstream hot gas temperature
  - Blowing ratio (cooling air flow)
- Examine interplay between air film cooling, backside impingement cooling, and through-hole convective cooling for TBC-coated substrate.
Approach

- Perform measurements in NASA GRC Mach 0.3 burner rig.
  - Vary flame temperature and blowing ratio.
- Perform measurements on TBC-coated superalloy plate with scaled up simple cooling hole geometry.
  - Initial testing of actual vane component did not produce effective air film cooling.

- Perform 2D temperature mapping using Cr-doped GdAlO$_3$ (Cr:GAP) phosphor thermometry.
  - GdAlO$_3$ exhibits orthorhombic perovskite crystal structure: gadolinium aluminum perovskite (GAP).
  - Ultrabright Cr:GAP luminescence emission enables surface temperature mapping using luminescence lifetime imaging by simply broadening the excitation laser beam to cover the region of interest.
  - Unbiased by emissivity changes and reflected radiation. ✓
  - Only applicable to steady state temperatures. ×
Luminescence Lifetime Image Stack

- $n$ images
- $t_0 =$ start of 1st exposure
- $\Delta t =$ frame interval
- $t_n = (n-1)\Delta t + t_0$
  - delay time after laser pulse for $n$th image in stack

Typical values:
- $n = 64$
- $t_0 = 0.1 \mu s$
- $\Delta t = 0.25$ to $100 \mu s$
- Frame interval = exposure = $\Delta t$
- Laser pulse frequency = 20 Hz
- 1 exposure/laser pulse (ICCD)
Luminescence Decay Curves from 25 μm GAP:Cr Coating in Furnace Time-Gated Imaging Averaged over 184x154 Pixel Area Extracted from 64-Frame Stacks

Fit to $I = I_0 e^{-t/\tau}$
Calibration of Decay Time vs. Temperature for Cr:GAP Coating
60 to 10% Initial Intensity Fitting Window

Two distinct regions
200°C<T<750°C: less temperature sensitive
T>750°C: more temperature sensitive

Fit to $\tau = \tau_2^E \frac{1 + 3e^{-\Delta E/kT}}{1 + \alpha e^{-\Delta E/kT} + \beta e^{-(\Delta E + \Delta E)/kT}}$

Cooling Effectiveness Measurements

**Conventional Air Film Cooling Effectiveness Test**

- Uniform mainstream flow (velocity & temperature)
- Typical surface temperatures: < 100°C
- Measure adiabatic air film cooling effectiveness, \( \eta = \frac{T_{\text{mainstream}} - T_{\text{adiabatic}}}{T_{\text{mainstream}} - T_{\text{surface}}} \)
- \( \eta \) is a fundamental characterization of pure air film cooling effectiveness
- Measure \( \eta \) as a function of blowing ratio, \( M \)
  \[ M = \frac{\rho_{\text{coolant}} v_{\text{coolant}}}{\rho_{\text{mainstream}} v_{\text{mainstream}}} \]

**Burner Rig Air Film Cooling Effectiveness Test**

- Divergent mainstream flow
- Typical temperatures: 600-1100°C
- Measure overall surface cooling effectiveness, \( \eta' \)
  \[ \eta' = \frac{T_{\text{uncooled}} - T_{\text{cooled}}}{T_{\text{uncooled}} - T_{\text{cooled enter}}} \]
- \( \eta' \) is a nonfundamental but realistic characterization of combined surface cooling effects
- Measure \( \eta' \) as a function of \( M' \)
  \[ M' = \frac{\rho_{\text{coolant}} v_{\text{coolant}}}{\rho_{\text{mainstream}} v_{\text{mainstream}}^\text{max}} \]

2D Temperature Mapping by Luminescence Lifetime Imaging

- Image stack collection
- Background subtraction
- Data filtering
- Pixel by pixel lifetime analysis
- Produce temperature and cooling effectiveness maps from decay time maps
Pre-Fit Data Filtering
Criteria for removing pixels unsuitable for temperature determination

Minimum absolute threshold
\[ I_{ij}(\text{frame 1}) < 2200 \]

Maximum final frame relative threshold
\[ I_{ij}(\text{last frame}) > 10\% \times I_{ij}(\text{first frame}) \]

Minimum number of frames in fitting interval
\[ 10\% \times I_{ij}(\text{first frame}) < I_{ij}(\text{frame } n) < 90\% \times I_{ij}(\text{first frame}) \]

Number of frames < 6

Insufficient signal

Too cold: need to extend to longer delay times after laser pulse

Too hot: need smaller increments of delay time

Post-fit temperature map

Example of better delay time range & increments
2D Temperature Maps from Luminescence Lifetime Imaging

- Multi-step procedure:
  - Step 1: Remove radiation background from each frame collected.

  Luminescence before background subtraction  Background (no laser)  Luminescence after background subtraction

  10 µs exposure 300 µs after laser pulse  1 cm

  - Step 2: Assemble stack of background-corrected time-gated images over sequence of incremented delay times.

  0 µsec

- Step 3: Preform pre-fit filtering.
  - Insufficient intensity, decay too fast or too slow
2D Temperature Maps from Luminescence Lifetime Imaging

- Step 4: Fit luminescence decay curve at each pixel to produce decay time map. Dynamic fitting window spans region between 60% and 10% of initial intensity. (Matlab routine).

- Step 5: Use calibration data to convert decay time map to temperature map (Matlab routine).

Find $T$ that gives known $\tau$ where $\tau = \frac{R}{\Delta E/kT} \frac{1+3e^{-\Delta E/kT}}{1+\alpha e^{-\Delta E/kT} + \beta e^{-(\Delta E+\Delta E)/kT}}$.

Temperature Map

Effect of Luminous Flame Bursts

Decay time temperature maps
95% confidence interval

Image Stack

$T_{\text{included}} - T_{\text{excluded}}$

Luminous flame streaks produce local temperature errors
~20°C too low.

Burning particles crossing field of view produce temperature map artifacts, can be mitigated by outlier removal.
$I_{ij}(t_n)$ is intensity of pixel $ij$ in frame $n$ of stack,

$t_n = n \Delta t + t_0$ where $\Delta t$ is frame interval and $t_0$ is 1st frame time;

$I_{ij}(t_n)$ is an outlier when $|I_{ij}(t_n) - I_{ij}^{\text{fit}}(t_n)| > 1.5 \sigma[I_{ij}(t_n) - I_{ij}^{\text{fit}}(t_n)]$
Air Film Cooling of TBC-Coated Surface
Results

- Examine changes in cooling effectiveness as a function of:
  - Mainstream hot gas temperatures: 1390, 1604, and 1722°C
  - Blowing ratio: $M' = 0$ to 1.1
Burner Rig 2D Temperature Maps

Signal attenuation due to flame deposit
How Many Frames Do We Really Need?
64 frames requires minimum 3 s, up to minutes at highest temperatures

2x binning

2x decimation

$n \times$ binning = $n \times$ faster acquisition

$n \times$ decimation = $n \times$ faster acquisition
$T_{\text{mainstream}} = 1390 \, ^\circ\text{C}$

$M' = 0.321$

**Burner Rig 2D Temperature Maps**

**Effect of Binning**

- 64 frames (no binning)
- 32 frames (2x binning)
- 16 frames (4x binning)
- 8 frames (8x binning)

Decay time temperature maps

1 cm

95% confidence interval

$\Delta T = T_{\text{binned}} - T_{\text{unbinned}}$

$n$x binning = $n$x faster acquisition

**Binning effects**
- Limits temperature range
- Modest decrease in precision
- Produces very little bias
$T_{\text{mainstream}} = 1390^\circ C$

$M' = 0.321$

**Burner Rig 2D Temperature Maps**

**Effect of Binning**

- **64 frames** (no binning)
- **32 frames** (2x binning)
- **32 frames** (2x decimation)

**Decay time temperature maps**

- **1 cm**

**95% confidence interval**

\[ \Delta T = T_{\text{binned}} - T_{\text{unbinned}} \]

$n x$ binning = $n x$ faster acquisition
Combined Cooling Effects Summary

- **Air film cooling**
  - Effectiveness initially increases with increasing $M$, then diminishes with jet lift-off.
  - Vortex-induced hot streaks appear near cooling holes. May be worse on TBC-coated surface.

- **Through-hole convective cooling**
  - Effectiveness increases rapidly at high $M$.
  - Not observed in conventional air film cooling measurements.

- **Backside impingement cooling**
  - Slowly increases with increasing $M$.

- **Cooling effectiveness shows similar dependence on blowing ratio over wide range of mainstream gas temperature.**

- **Effect of TBC on other cooling mechanisms**
  - Will decrease air film cooling effectiveness.
  - Will increase through hole convective cooling effectiveness – may be useful for showerhead cooling.
Future Direction
Add Metal Surface Temperature Maps

Mainstream Gas Flow
\( T_{\text{mainstream}} \)

\( T_{\text{air film}} \)

\( T_{\text{surface}} \)

Cr:GAP

Doped YSZ Phosphor

\( T_{\text{coolant gas}} \)

Surface cooling effectiveness from Cr:GAP layer:
\[
\eta' = \frac{T_{\text{surface uncooled}} - T_{\text{surface cooled}}}{T_{\text{surface uncooled}} - T_{\text{coolant enter}}}
\]

Metal cooling effectiveness from doped YSZ layer:
\[
\Phi' = \frac{T_{\text{metal uncooled}} - T_{\text{metal cooled}}}{T_{\text{metal uncooled}} - T_{\text{coolant enter}}}
\]
Conclusions

- Successfully demonstrated 2D temperature mapping by Cr:GAP phosphor thermometry with high resolution (temperature, spatial, but not temporal) in presence of strong background radiation associated with combustor burner flame.
- Can be used as new tool for studying/optimizing non-additive interplay of cooling mechanisms for TBC-coated components.
  - TBC
  - Air film
  - Through-hole convection
  - Backside impingement
