A fluidic oscillator having independent frequency and amplitude control includes a fluidic-oscillator main flow channel having a main flow inlet, a main flow outlet, and first and second control ports disposed at opposing sides thereof. A fluidic-oscillator controller has an inlet and outlet. A volume defined by the main flow channel is greater than the volume defined by the controller. A flow diverter coupled to the outlet of the controller defines a first fluid flow path from the controller's outlet to the first control port and defines a second fluid flow path from the controller's outlet to the second control port.

FIG. 2
FLUIDIC OSCILLATOR HAVING DECOUPLED FREQUENCY AND AMPLITUDE CONTROL

CROSS-REFERENCE TO RELATED PATENT APPLICATIONS

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

The invention was made by an employee of the United States Government and may be manufactured and used by or for the Government of the United States of America for governmental purposes without the payment of any royalties thereon or therefor.

BACKGROUND OF THE INVENTION

Field of the Invention

This invention relates to fluidic oscillators. More specifically, the invention is a fluidic oscillator having frequency control features that allow the oscillator’s frequency to be controlled independently of the oscillator’s mass flow rate or amplitude.

Description of the Related Art

In the 1900s, fluidic oscillators were developed for use as logical function operators. More recently, fluidic oscillators have been proposed for use as active flow control devices where an oscillator’s jet output is used to control a fluid flow (e.g., gas or liquid). FIGS. 1A-1C schematically illustrate the basic operating principles of a fluidic oscillator. Briefly, fluid flow 100 enters a fluidic oscillator 10 at its input 10A and attaches to either sidewall 12 or 14 (e.g., right sidewall 14 in the illustrated example) due to the Coanda effect as shown in FIG. 1A. A backflow 102 develops in a right hand side feedback loop 18. Backflow 102 causes fluid flow 100 to detach from right sidewall 14 (FIG. 1B) and attach to left sidewall 12 (FIG. 1C). When fluid flow 100 attaches to left sidewall 12, a backflow 104 develops in left hand side feedback loop 16 which will force fluid flow 100 to switch back to its initial state shown in FIG. 1A. As a result of this activity, fluid flow 100 oscillates/sweeps back and forth at the output 10B of oscillator 10.

For conventional fluidic oscillators, the frequency of the oscillations is directly dependent on the supply pressure and hence mass flow rate (or amplitude) of the oscillator. However, for practical applications, it is highly desirable to decouple the frequency and amplitude of the oscillator so that the frequency of the oscillator could be controlled independently of its amplitude. A frequency-decoupled fluidic oscillator could thus deliver desired mass flow rates without changing the frequency or could deliver desired frequency oscillations at desired mass flow rates.

For conventional fluidic oscillators, the frequency of the oscillations is directly dependent on the supply pressure and hence mass flow rate (or amplitude) of the oscillator. However, for practical applications, it is highly desirable to decouple the frequency and amplitude of the oscillator so that the frequency of the oscillator could be controlled independently of its amplitude. A frequency-decoupled fluidic oscillator could thus deliver desired mass flow rates without changing the frequency or could deliver desired frequency oscillations at desired mass flow rates.

BRIEF SUMMARY OF THE INVENTION

Accordingly, it is an object of the present invention to provide a fluidic oscillator having frequency control features.

Another object of the present invention is to provide a fluidic oscillator whose frequency is independent of the oscillator’s mass flow rate or amplitude.

Still another object of the present invention is to provide a method of decoupling frequency control from amplitude control in a fluidic oscillator.

Other objects and advantages of the present invention will become more obvious hereinafter in the specification and drawings.

In accordance with the present invention, a fluidic oscillator having independent frequency and amplitude control includes a fluidic-oscillator main flow channel having a main flow inlet and a main flow outlet. The main flow channel has a first control port and a second control port disposed at opposing sides thereof. The main flow channel defines a first volume between the main flow inlet and the main flow outlet. A fluidic-oscillator controller has an inlet and outlet with a second volume being defined between its inlet and outlet. The first volume defined by the main flow channel is greater than the second volume defined by the controller. A flow diverter coupled to the outlet of the controller defines a first fluid flow path from the outlet to the first control port and defines a second fluid flow path from the outlet to the second control port.

APPLICATIONS

Another object of the present invention is to provide a fluidic oscillator having frequency control features.

Accordingly, it is an object of the present invention to provide a fluidic oscillator having frequency control features.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A-1C schematically illustrate the operating principles of a fluidic oscillator in accordance with the prior art; FIG. 2 is a schematic illustration of a fluidic oscillator having independent frequency and amplitude control in accordance with an embodiment of the present invention; FIG. 3 is an exploded perspective view of a multi-layer fluidic oscillator having independent frequency and amplitude control in accordance with an embodiment of the present invention; FIG. 4 is an isolated perspective view of the fluidic-oscillator controller portion of the present invention; and FIG. 5 is a plan view of the fluidic-oscillator controller portion of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Referring again to the drawings and more specifically to FIG. 2, a fluidic oscillator for generating an oscillating jet whose frequency is controlled independently of the jet’s mass flow rate (or amplitude) in accordance with an embodiment of the present invention is illustrated schematically and is referenced generally by numeral 20. Fluidic oscillator 20 includes a main oscillating-flow channel 22, a frequency-controlling fluidic oscillator 24 (or fluidic-oscillator controller as it will also be referred to herein), and a fluid flow diverter 26 fluidically coupling frequency-controlling fluidic oscillator 24 to main flow channel 22.

Main oscillating-flow channel 22 is configured as the main flow channel of a conventional fluidic oscillator, but does not have conventional feedback loops coupled thereto. That is, channel 22 only has an inlet 22A for receiving a (main or amplitude-controlling) fluid flow 100, an outlet 22B through which the fluid flow will exit as an oscillating jet 110, opposing Coanda surfaces 22C/22D, and opposing-
Fluid flow diverter 26 is a fluid-flow splitting device used to direct oscillating jet 210 in an alternating fashion to control ports 22E and 22F of main oscillating-flow channel 22. The frequency of oscillating jet 210 serves as the frequency control for main oscillating-flow channel 22 producing oscillating jet 110. Since frequency-controlling fluidic oscillator 24 only needs to disturb the flow moving through channel 22 (i.e., analogous to disruptions provided by feedback loops in conventional fluidic oscillators), a relatively small mass flow through oscillator 24 is all that is required. In general, the smaller mass flow for frequency control is achieved when the volume \( V_{24} \) is at least twice as large as the volume \( V_{22} \). However, it is to be understood that the volume differential between main oscillating-flow channel 22 and fluidic oscillator 24 can be tailored for a specific application without departing from the scope of the present invention.

A variety of approaches can be used to construct a frequency-controlled fluidic oscillator 24 in accordance with the present invention. By way of example, a layered-construct fluidic oscillator 50 will be explained herein with simultaneous reference to FIGS. 3-5 where common reference numerals are used in the various views. Fluidic oscillator 50 is constructed from three layers/panels 60, 70, and 80, where panels 60 and 80 sandwich panel 70. Panels 60 and 80 are essentially covers for oscillator 50 with each of panels 60 and 80 having a respective fluid-flow inlet hole 62 and 82 formed therethrough.

In general, panel 70 has the main oscillating-flow channel’s shape/volume formed on one face thereof and the frequency-controlling fluidic oscillator’s shape/volume formed on the opposing face thereof. When panels 60 and 80 sandwich panel 70, the main oscillating-flow channel and frequency-controlling fluidic oscillator of oscillator 50 are formed. The present invention’s fluid flow diverter is formed in panel 70. More specifically, one face of panel 70 defines a plenum region 72 that receives incoming fluid flow 100 (i.e., the main or amplitude-controlling fluid flow) via inlet hole 62. Main oscillating-flow channel 22 has its inlet 22A in fluid communication with plenum region 74. As would be understood in the art, fluidic oscillator 24 defines conventional feedback loops 24C and 24D.

Diverter 26 is in fluid communication with outlet 24B of frequency-controlling fluidic oscillator 24 and control ports 22E/22F of main oscillating-flow channel 22. More specifically, a first flow path 26A is formed in and through panel 70 is directed from outlet 24B to control port 22E, while a second flow path 26B is formed in and through panel 70 is directed from outlet 24B to control port 22F. In this way, the frequency-controlling oscillating jet 210 is supplied to control ports 22E/22F in an alternating fashion in accordance with the frequency of oscillating jet 210.

The advantages of the present invention are numerous. Frequency control of the fluidic oscillator’s main oscillating-flow channel is decoupled from its amplitude. In this way, a desired mass flow rate (i.e., through the main oscillating-flow channel) can be delivered without changing the frequency thereof, or the frequency can be changed while maintaining a particular mass flow rate (i.e., through the main oscillating-flow channel). The approach is simple and requires no moving parts.

Although the invention has been described relative to specific embodiments thereof, there are numerous variations and modifications that will be readily apparent to those skilled in the art in light of the above teachings. It is therefore to be understood that, within the scope of the appended claims, the invention may be practiced other than as specifically described.

What is claimed as new and desired to be secured by Letters Patent of the United States is:

1. A fluidic oscillator having independent frequency and amplitude control, comprising:
   a fluidic-oscillator main flow channel having a main flow inlet configured to receive an amplitude controlling fluid flow and a main flow outlet, said main flow channel having a first control port and a second control port disposed at opposing sides thereof, said main flow channel defining a first volume between said main flow inlet and said main flow outlet;
   a first plenum in fluid communication with said main flow inlet;
   a fluidic-oscillator controller having an inlet configured to receive a frequency controlling fluid flow and outlet wherein a second volume is defined between said inlet and said outlet, and wherein said first volume is at least two times greater than said second volume;
   a second plenum in fluid communication with said inlet of said controller; and
   a flow diverter coupled to said outlet of said controller, said first control port, and said second control port, said flow diverter defining a first fluid flow path from said outlet to said first control port and defining a second fluid flow path from said outlet to said second control port, wherein said amplitude controlling fluid controls an amplitude of a fluid flow through said main flow channel and said frequency controlling fluid flow controls a frequency of said fluid flow through said main flow channel, and
   wherein said amplitude controlling fluid flow is independent of said frequency controlling fluid flow.

2. A fluidic oscillator as in claim 1, wherein said main flow channel, said flow diverter, and said controller are formed using a layered construction.

3. A fluidic oscillator as in claim 1, wherein said main flow channel and said first plenum are formed using a first fluid communication with plenum region 74. As would be understood in the art, fluidic oscillator 24 defines conventional feedback loops 24C and 24D.
panel and a second panel, wherein said controller and said second plenum are formed using said second panel and a third panel, and wherein said flow diverter is formed using said second panel.

4. A fluidic oscillator having independent frequency and amplitude control, comprising:
   a fluidic-oscillator main flow channel having a main flow inlet configured to receive an amplitude controlling fluid flow and a main flow outlet, said main flow channel having a first control port and a second control port disposed at opposing sides thereof; said main flow channel defining a first volume between said main flow inlet and said main flow outlet;
   a fluidic-oscillator controller having an inlet configured to receive a frequency controlling fluid flow and an outlet wherein a second volume is defined between said inlet and said outlet, and wherein said first volume is greater than said second volume; said controller adapted to have a fluid flow move from said inlet to said outlet wherein said controller generates an oscillating output at said outlet, said oscillating output having a frequency associated therewith; and
   a flow diverter coupled to said outlet of said controller, said first control port, and said second control port, for directing said oscillating output in an alternating fashion in accordance with said frequency thereof to said first control port and said second control port, wherein said amplitude controlling fluid controls an amplitude of a fluid flow through said main flow channel and said frequency controlling fluid flow controls a frequency of said fluid flow through said main flow channel, and wherein said amplitude controlling fluid flow is independent of said frequency controlling fluid flow.

5. A fluidic oscillator as in claim 4, further comprising a first plenum in fluid communication with said main flow inlet and a second plenum in fluid communication with said inlet of said controller.

6. A fluidic oscillator as in claim 4, wherein said first volume is at least two times greater than said second volume.

7. A fluidic oscillator as in claim 4, wherein said main flow channel, said flow diverter, and said controller are formed using a layered construction.

8. A fluidic oscillator as in claim 5, wherein said main flow channel and said first plenum are formed using a first panel and a second panel, wherein said controller and said second plenum are formed using said second panel and a third panel, and wherein said flow diverter is formed using said second panel.

9. A method for independently controlling frequency and amplitude of a fluidic oscillator, comprising:
   providing a fluidic-oscillator main flow channel having only a main flow inlet, a main flow outlet, a first control port, and a second control port wherein said first control port and said second control port are disposed at opposing sides thereof; said main flow channel defining a first volume between said main flow inlet and said main flow outlet;
   providing a fluidic-oscillator controller having an inlet and outlet wherein a second volume is defined between said inlet and said outlet, and wherein said first volume is greater than said second volume; providing a fluidic-oscillator controller having an inlet and outlet wherein a second volume is defined between said inlet and said outlet, and wherein said first volume is greater than said second volume;
   providing a flow diverter coupled to said outlet of said controller, said flow diverter defining a first fluid flow path from said outlet to said first control port and defining a second fluid flow path from said outlet to said second control port;
   delivering a first fluid flow to said main flow inlet;
   delivering a second fluid flow to said inlet of said controller; and
   selectively changing at least one of said first fluid flow and said second fluid flow, wherein changes in said first fluid flow affect amplitude of an oscillating fluid flow exiting said main flow outlet, and wherein changes in said second fluid flow affect frequency of said oscillating fluid flow.

10. A method according to claim 9, wherein said first volume is at least two times greater than said second volume.
