GRAM Virtual Workshop, September 21, 2017
Venus-GRAM

- Venus Global Reference Atmospheric Model (Venus-GRAM) is an engineering-level atmospheric model developed by MSFC that is widely used for diverse mission applications including:
  - Systems design
  - Performance analysis
  - Operations planning for aerobraking, Entry, Descent and Landing, and aerocapture
- Is not a forecast model
- Outputs include density, temperature, pressure, wind components, and chemical composition
- Provides dispersions of thermodynamic parameters, winds, and density
- Optional trajectory and auxiliary profile input files
- Has been used in multiple studies and proposals including NASA Engineering and Safety Center (NESC) Autonomous Aerobraking and various Discovery proposals
- Released in 2005
- Available at: https://software.nasa.gov/software/MFS-32314-1
Venus-GRAM Atmosphere (0-250 km)

- From the surface to 250 km, Venus-GRAM atmosphere model is based on the Venus International Reference Atmosphere (VIRA)
- Lower atmosphere: 0 - 100 km
  - VIRA data depends on height and latitude
- Middle-atmosphere: 100 - 150 km
  - VIRA data depends on height and local solar time (LST = 0 or LST = 12 Venus hours)
- Upper-altitude: 150 - 250 km
  - VIRA data depends on height and solar zenith angle
- Venus-GRAM ensures smooth variation between height regions by averaging values at the two transition heights (100 km and 150 km)
- Version of VIRA in Venus-GRAM includes Pioneer Venus Orbiter and Probe data as well as Venera probe data
  - Does not include a solid planet model, nor a high resolution gravity model
Venus-GRAM Thermosphere (250–1000 km)

• The Venus-GRAM thermosphere (250 - 1000 km) is based on a MSFC-developed model
• Model assumptions:
  – VIRA conditions and constituents at 250 km are used as lower boundary values
  – Constant (exospheric) temperature is assumed above 250 km (exospheric temperature = local VIRA temperature at 250 km)
  – Hydrostatic conditions are computed separately for each constituent (diffusive separation)
  – Total pressure is computed from constituent partial pressures
  – Mass density is computed from constituent number densities
Venus-GRAM Thermosphere Model

- Exospheric temperature is highest (about 300K) for a few hours on either side of solar noon
- Normally, hydrostatic conditions mean that densities at high altitudes are larger for higher exospheric temperatures
  - Density increases as the entire atmospheric column expands, because of larger temperatures
- Above about 300 km altitude, density is at a relative minimum near solar noon, despite the higher values of exospheric temperature at this time of day

Contours of Venus thermospheric density versus altitude and time of day, and a plot of exospheric temperature (red line) versus time of day, at Latitude=0, Ls=0 (Spring equinox). Density contours are labeled in units of Log base-10 of density in kg/m$^3$. 

Log$_{10}$(Density, kg/m$^3$) or Exospheric Temperature Ls=0 Lat=0
Venus-GRAM Thermosphere Model

- Anomaly can be explained by examining the relationship between the mean molecular weight (M) and density scale height (H) versus altitude and local time
  - H is proportional to T / M, where T is temperature
  - Higher exospheric temperature near noon would tend to make H larger near this time of day
  - Higher values of M near noon would tend to make H smaller near this time of day
Venus-GRAM Thermosphere Model

- For conditions of Ls=0, Lat=0, the M effect dominates, making H smaller near noon
- Density varies with altitude z as $\exp(-z/H)$
  - Smaller H near noon means that density falls off more rapidly near noon than in morning or afternoon.
- Thus, above about 300 km altitude, density is at a relative minimum near solar noon

Contour map of Venus density scale height (H) versus altitude and time of day.
Venus-GRAM Data Upgrades

• Evaluating several Venus atmosphere models and data sources that can be utilized to update Venus-GRAM:
  – Updated VIRA model in work (Sanjay Limaye et al.)
  – Earth observation data of Venus
  – Venus Express data
  – Magellan surface and gravity field data
  – Updated Venus Thermospheric General Circulation Model (VTGCM) and Venus General Circulation Models (VGCMs)
  – Development of a Venus Global Ionosphere-Thermosphere Model (V-GITM) (Steve Bougher (University of Michigan))

• Additional suggestions would be appreciated
Venus-GRAM Capability Upgrades

• Convert model code from Fortran to C++
  – Easier to incorporate in trajectory simulation software
• Identify high priority items that would enable mission modeling that are not currently available. Examples include:
  – Incorporating a higher resolution topography model for probe mission analysis
  – Utilizing Venus Express data to build sets of auxiliary profiles for representation of mean atmospheric conditions in Venus-GRAM
  – Characterizing observed atmospheric variability and update perturbation models for density, temperature, and winds in Venus-GRAM
• Additional suggestions would be appreciated
