APPENDIX A Pisgah Lava Cave Map ....................................................................................................... 6
1 INTRODUCTION

As part of the science case study for the Networked Constellations initiative, a team of JPL scientists explore the possibility of a mission to study the lava caves on Mars. Natural caves on Mars and the Moon present a unique opportunity to learn about the planetary geology and to provide a shelter for human explorers. Due to power and communication challenges, a network of assets has significant advantages over a single asset sent inside a cave.

However, communication between the assets and the data downlink present significant difficulties due to the presence of rough walls, boulders, and other obstacles with unknown dielectric constant inside a typical cave, disturbing the propagation of the radio waves. A detailed study is needed to establish the limitations of the current communication technologies and to develop requirements for the new communication technology applicable to the cave environment.

On May 4 of 2017, Konstantin Belov, Doug Ellison, and Abby Fraeman visited a lava cave in Pisgah, CA. The purpose of the visit was to build a 3D map of the cave, which could be used to create a model of radio wave propagation, and to conduct a series of communication tests using off-the-shelf equipment to verify the in-cave communication challenges. This experiment should be considered as a simple “proof of concept” and is the subject of this report.

2 EQUIPMENT

The following equipment was used during the test:

- Netgear R7000 2.4/5 GHz router
- USB3 portable hard drive
- Li-ion 44 Wh rechargeable battery
- Different antennas tuned to 2.4 and 5 GHz bands
- MacBook Pro laptop
- Different antenna adapters

The Netgear R7000 is a robust flexible network router supporting 2.4 and 5 GHz WiFi bands. It has 3 antennas, allowing us to change the signal polarization if needed, as well as a USB3 port to connect the external storage. We used a traditional spinning USB3 hard drive with 1 TB capacity. The power to the router and the attached hard drive was supplied by a 44 Wh Li-ion rechargeable battery. The battery has a standard 12 V outlet socket and a cable with the standard 12 V plug. The router is rated at 3.5 A max current at 12 V. No modification to the battery, the router, or the power cable was needed. The battery was able to supply the power during the whole duration of the test, which lasted more than 5 hours.

Although several additional antennas were available for the test, the limited manpower combined with the difficult terrain inside the cave made switching the antennas cumbersome, and only the standard antennas were used for most of the experiment.
The router with the attached hard drive powered by the Li-ion battery formed one communication station, while a MacBook Pro laptop was used as the second station for the experiment. The stations were placed at different locations inside the cave and the two tests were conducted at 2.4 and 5 GHz frequencies at each location: 1) a ping test to check for the packet loss, and 2) a data speed transfer test. The total of 14 locations were tested.

3 RESULTS

The results of the tests together with the description of the signal paths are summarized in Table 1 below. The distances between the checkpoints are shown in Table 2, while the map of the cave with the checkpoints marked is shown in Appendix A. The following are some examples of the tests conducted:

3.1 TEST 1

The router was placed at Checkpoint E, under the cave ceiling between the first and second room (see Figure 1). Two 5 GHz chip antennas were connected. Since only two such antennas were available, the router’s third antennas input was terminated by a 50 Ohm plug. The laptop was located 4 m from the router in direct field of view. The communication was established initially at 5 GHz, but then the connection was lost.

After changing the antennas back to the standard ones, it was decided to conduct the rest of the tests with the standard antennas because the more advanced directive antennas on hand would require careful tuning and only one team member was available for the communication tests. The rest of the team was busy with 3D mapping, which also proved to be very labor intensive.

### 3.3 TESTS 11 AND 12

For Tests 11 and 12, the router was placed in the next room inside the cave. In both tests, the router was not in the field of view of the laptop. Test 12 goes deeper into the cave behind the turn. See Figure 3. The results of the tests are in Table 1.

### 3.4 TESTS 13 AND 14

These tests were conducted with the router in the same location as in Tests 11 and 12, but the laptop was placed in the last room of the cave, Room 4. In addition to the previous obstruction by the turn and the elevation change, the narrow passage into the room created an additional obstacle for the signal. For Test 14, the router was moved closer to the laptop, to Checkpoint H, but the wall obstruction was still present.

The results of the test are provided in the Table 1, while the laptop location is shown in Figure 4.
4 DISCUSSION

The field experiment showed that it is possible to establish a reliable communication inside the lava cave using commercial equipment utilizing the standard WiFi protocols. The communication range was about 10–30 m depending on the cave geometry.

The experiment also showed that complicated cave geometry and obstructions does not necessarily prevent high rate of data transfer; however, the data rate is reduced if obstructions are present. Double obstructions proved problematic for establishing any communication. Further analysis of the electric field properties is required to understand how various geometry features affect the link quality and to develop an advanced protocol to mitigate the communication challenges in the presence of complicated geometry that obstructs the signal.
